⁹⁶ **Executive Summary**

executive-summary

⁹⁷ **Stock**

stock

⁹⁸ This assessment reports the status of the gopher and black-and-yellow rockfish
⁹⁹ complex (GBYR, *Sebastodes carnatus*/*Sebastodes chrysomelas*) resource as in U.S. waters off the
¹⁰⁰ coast of California south of Cape Mendocino (40°10' N. latitude) using data through 2018.
¹⁰¹ Both gopher and black-and-yellow rockfishes are most abundant north of Point Conception
¹⁰² (34°27' N. latitude) and are rare north of Point Arena (38°57' N. latitude). The range of
¹⁰³ gopher rockfish extends into Baja California, but the black-and-yellow rockfish are rare south
¹⁰⁴ of Point Conception.

¹⁰⁵ **Catches**

catches

¹⁰⁶ Information on historical landings of GBYR are available back to 1916 (Table [a](#)). The
¹⁰⁷ recreational fleet began ramping up in the 1950s and has fluctuated over the the last 50 years
¹⁰⁸ (Figure [a](#)). The majority of gopher and black-and-yellow rockfish recreational landings are
¹⁰⁹ from north of Point Conception.

¹¹⁰ Commercial landings were small during the years of World War II, ranging between 4 to 28
¹¹¹ metric
¹¹² tons (mt) per year (Figure [b](#)). Commercial landings increased after World War II and show
¹¹³ periods of cyclical catch for gopher and black-and-yellow rockfishes. The commercial live fish
¹¹⁴ fishery began in the early 1990s, with the first reported live landings in 1993. Since then the
¹¹⁵ commercial catch has been dominated by the live fish fishery, with minimal landings of dead
¹¹⁶ gopher or black-and-yellow rockfishes. Estimates of total mortality of commercial discards
¹¹⁷ were available starting in 2004, and were estimated prior to then. The catches aggregated
¹¹⁸ by fleets modeled in this assessment can be found in Figure [c](#).

¹¹⁹ Since 2000, annual total landings of catch and discards of GBYR have ranged between 70-169
¹²⁰ mt, with landings (catch + discards) in 2018 totaling 92 mt.

Figure a: Catch history of GBYR for the recreational fleet. | fig:Exec_catch1

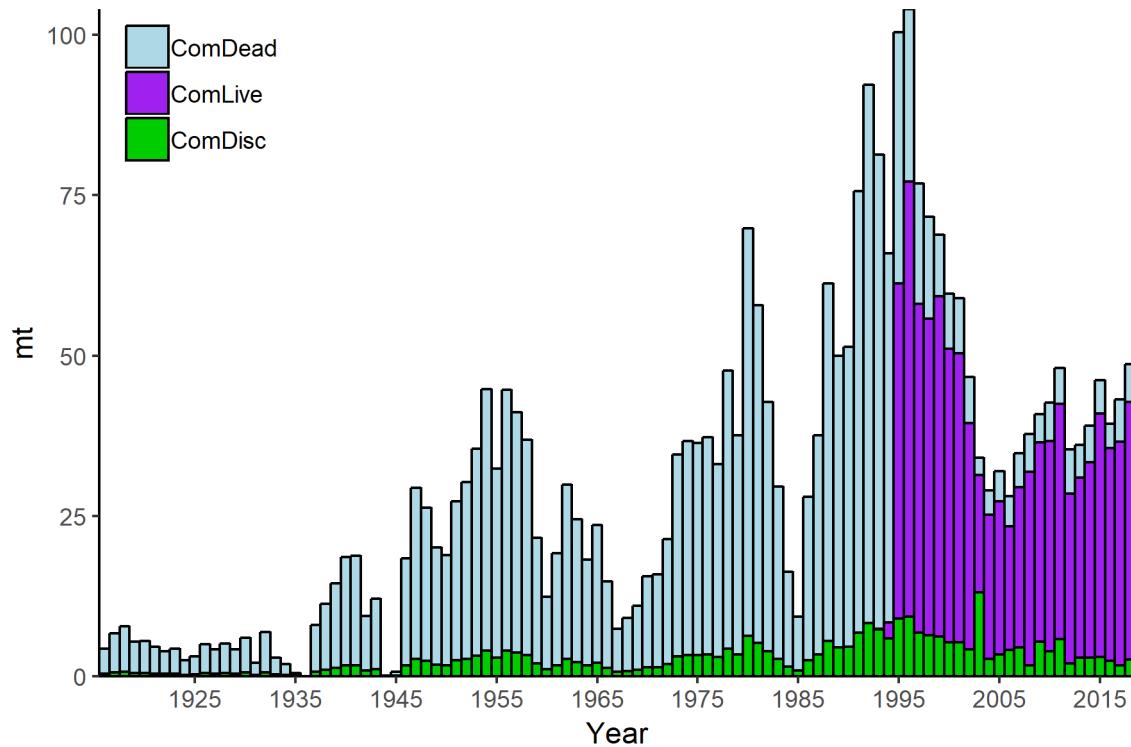

Figure b: Catch history of GBYR for the commercial fleet by dead and live landings, and discards. Catches in 1936 and 1946 were minimal. ^{fig:Exec_catch2}

Table a: Recent GBYR landings (mt) by fleet.

Year	Commercial Retained	Commercial Discard	Recreational North	Recreational South	<u>tab:Exec_catch</u>
2009	35.62	5.38	65.64	4.30	110.93
2010	38.83	3.92	106.76	3.90	153.41
2011	42.39	5.72	76.16	10.24	134.52
2012	33.55	1.93	48.25	9.89	93.62
2013	33.45	2.85	38.43	8.86	83.59
2014	36.40	2.85	56.96	9.06	105.27
2015	43.25	2.93	58.09	5.00	109.27
2016	36.96	2.42	65.72	6.57	111.67
2017	42.04	1.65	49.36	11.15	104.19
2018	47.00	2.54	36.48	6.30	92.32

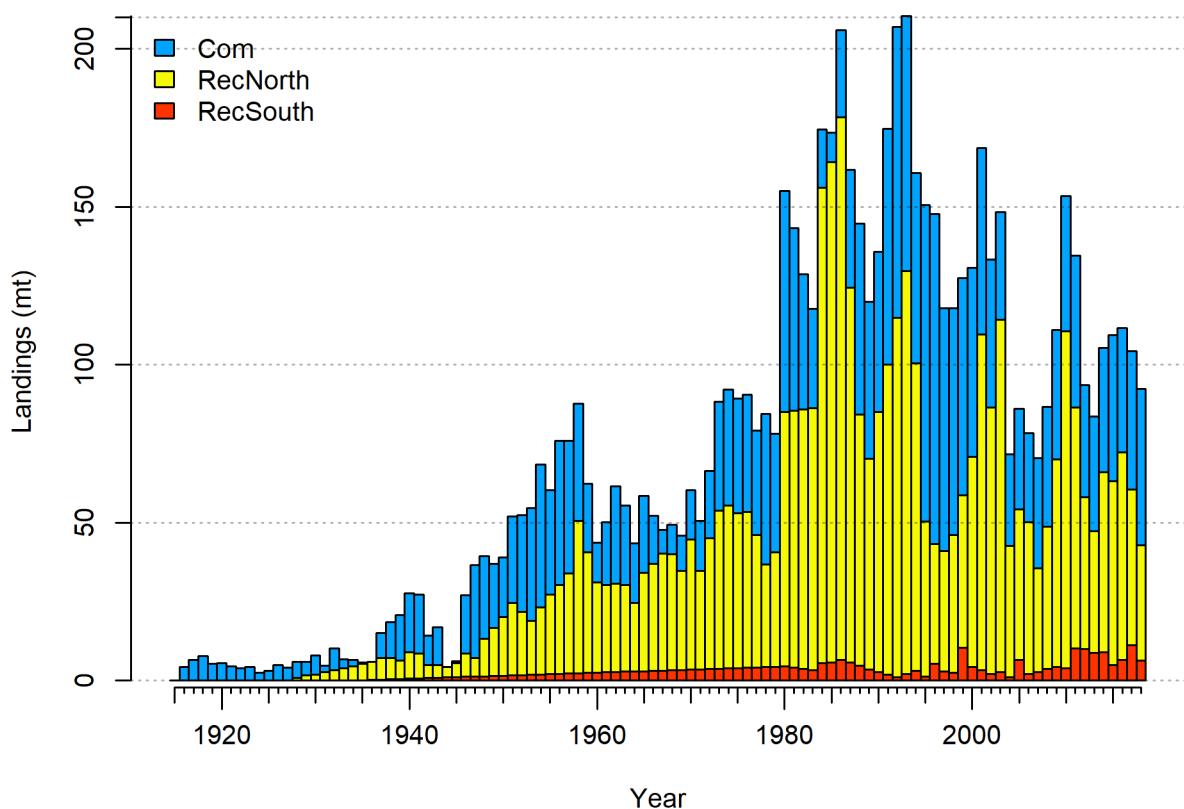

Figure c: Catch history of GBYR in the model. [fig:r4ss_catches](#)

¹²¹ **Data and Assessment**

data-and-assessment

¹²² Gopher rockfish north of Point Conception ($34^{\circ}27'$ N. latitude) was first assessed as a full
¹²³ stock assessment in 2005 (Key et al. 2005) using SS2 (version 1.19). The assessment was
¹²⁴ sensitive to the CPFV onboard observer index of abundance (referred to as Deb Wilson-
¹²⁵ Vandenberg's onboard observer index in this assessment). The final decision table was based
¹²⁶ around the emphasis given to a fishery-dependent index of abundance for the recreational
¹²⁷ fleet. The stock was found to be at 97% depletion.

¹²⁸ Gopher rockfish south of Point Conception was assessed as a data poor species in 2010 (Dick
¹²⁹ and MacCall 2010). A Depletion-Corrected Average Catch (DCAC) model was used due to
¹³⁰ time constraints. The mean yield from the DCAC distribution was 25.5 mt.

¹³¹ This is the first full assessment to include data for black-and-yellow rockfish. Black-and-
¹³² yellow rockfish was assessed coastwide as a data poor species using Depletion-Based Stock
¹³³ Reduction Analysis (DB-SRA) (Dick and MacCall 2010). The DB-SRA model assigned a
¹³⁴ 40% probability that the then recent (2008-2009) catch exceeded the 2010 OFL.

¹³⁵ This assessment covers the area from Cape Mendocino to the U.S./Mexico border (Figure
¹³⁶ d). The length composition data suggested that while the lengths of gopher and black-and-
¹³⁷ yellow rockfish were similar, fish encountered south of Point Conception were smaller. The
¹³⁸ similarity of the length distributions between species and among modes within a region were
¹³⁹ similar and justified one combined recreational fleet within each of the two regions (north
¹⁴⁰ and south of Point Conception).

¹⁴¹ This stock assessment retains a single fleet for the commercial fishery, including discards.
¹⁴² Data on commercial discards were not available for and not included in the 2005 assessment.
¹⁴³ The decision to retain one commercial fleet was made by examining the length distributions
¹⁴⁴ across species, fishing gears, and space, i.e., north and south of Point Conception. There is
¹⁴⁵ very little difference between the length composition of gopher and black-and-yellow rockfish
¹⁴⁶ landed in the commercial fleet north of Point Conception.

¹⁴⁷ A number of sources of uncertainty are addressed in this assessment. This assessment in-
¹⁴⁸ cludes length data, estimated growth, an updated length-weight curve, an updated maturity
¹⁴⁹ curve, a number of new indices, and new conditional age-at-length data.

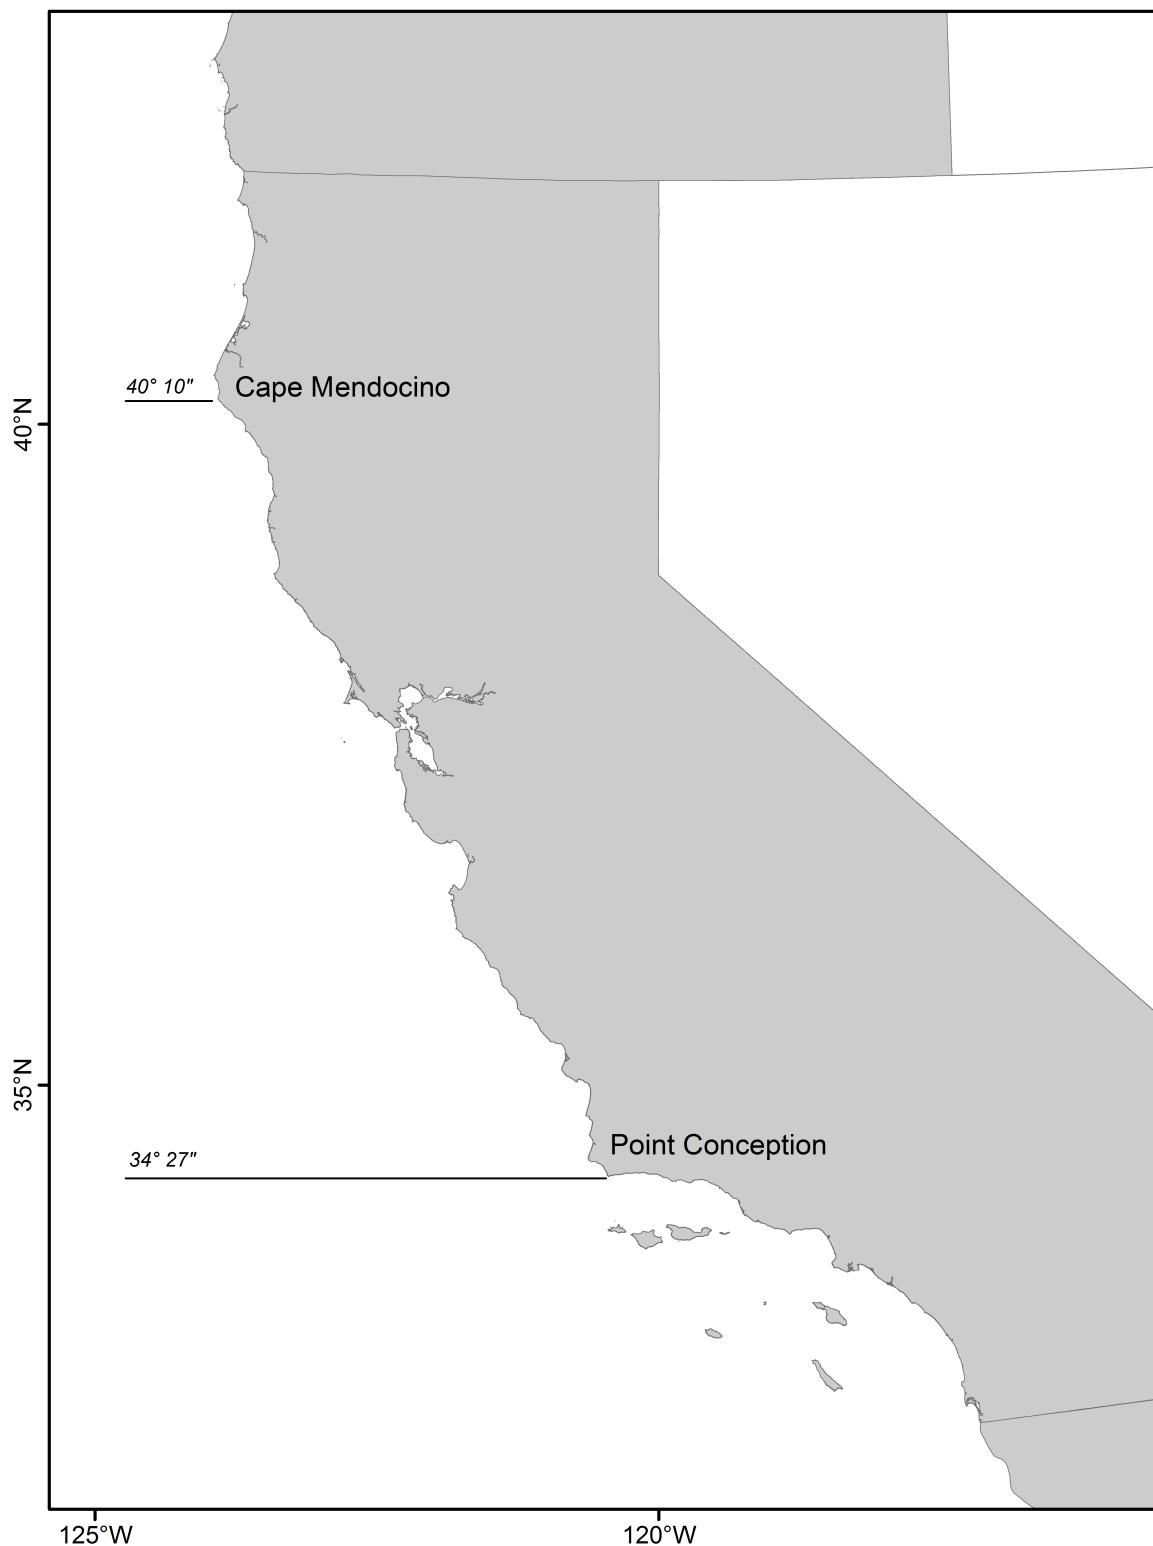

Figure d: Map depicting the core distribution of gopher and black-and-yellow rockfishes. The stock assessment is bounded at Cape Mendocino in the north to the U.S./Mexico border in the south. [fig:assess_region_map](#)

150 **Stock Biomass**

stock-biomass

151 The predicted spawning output from the base model generally showed a slight decline prior
152 to 1978, when the recruitment deviations were first estimated (Figure e and Table b). The
153 stock declined from 1978 to 1994, followed by a period increase from 1995 to 2003. From
154 2004-2018 the stock has been in decline, though increased in total biomass since 2016 and
155 stable spawning output since from 2018 to 2019. The 2019 estimated spawning output
156 relative to unfished equilibrium spawning output is above the target of 40% of unfished
157 spawning output at 43.82 (95% asymptotic interval: 33.57-54.06) (Figure f). Approximate
158 confidence intervals based on the asymptotic variance estimates show that the uncertainty
159 in the estimated spawning output is high, (95% asymptotic interval: 337-767 million eggs).

Table b: Recent trend in beginning of the year spawning output and depletion for the model
for GBYR.

Year	Spawning Output (million eggs)	~ 95% confidence interval	Estimated depletion	<small>tab:SpawningDeplete_mod1</small> ~ 95% confidence interval
2010	882	597 - 1168	69.99	58.05 - 81.92
2011	817	548 - 1086	64.77	53.48 - 76.06
2012	761	507 - 1014	60.33	49.63 - 71.03
2013	727	486 - 968	57.66	47.5 - 67.81
2014	697	466 - 928	55.31	45.56 - 65.05
2015	655	434 - 877	51.98	42.4 - 61.55
2016	614	399 - 828	48.69	39.16 - 58.22
2017	576	367 - 786	45.70	36.12 - 55.28
2018	553	344 - 762	43.85	34.08 - 53.63
2019	552	337 - 767	43.82	33.57 - 54.06

Spawning output with ~95% asymptotic intervals

Figure f: Estimated percent depletion with approximate 95% asymptotic confidence intervals (dashed lines) for the base case assessment model. fig:Re1Deplete_all

160 **Recruitment**

recruitment

161 Recruitment deviations were estimated from 1979-2018 (Figure g and Table c). There are
162 estimates of very strong recruitment in 1991. Recruitment pulses were estimated for a
163 number of other years including 1994-1995 and 2014-2015.

Table c: Recent recruitment for the GBYR assessment.

Year	Estimated Recruitment (1,000s)	~ 95% confidence interval
2010	2451	1257 - 4779
2011	2014	983 - 4127
2012	1800	761 - 4258
2013	1589	676 - 3734
2014	4568	2519 - 8284
2015	5264	2985 - 9282
2016	2487	1274 - 4857
2017	3701	1976 - 6935
2018	1432	664 - 3089
2019	2778	1086 - 7111

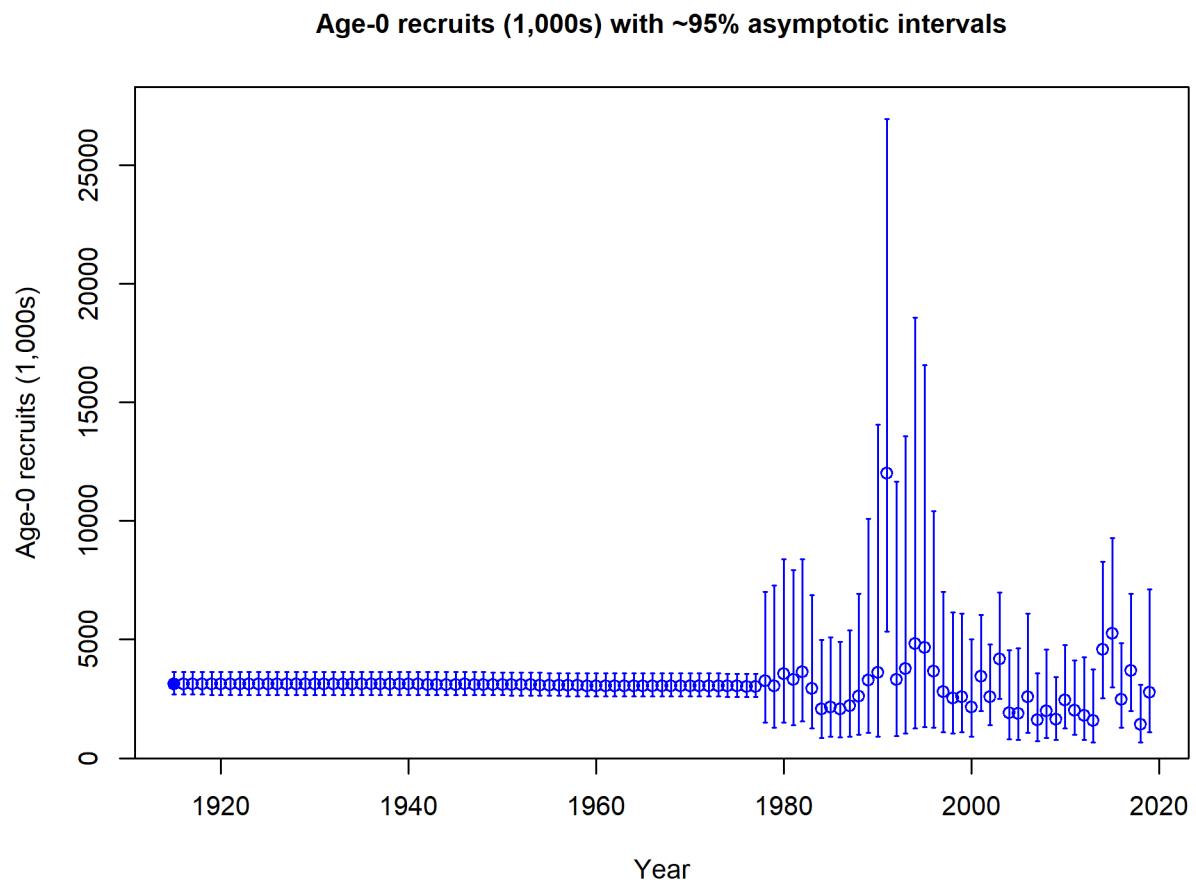

Figure g: Time series of estimated GBYR recruitments for the base-case model with 95% confidence or credibility intervals. [fig:Recruits_all](#)

¹⁶⁴ **Exploitation status**

exploitation-status

¹⁶⁵ Harvest rates estimated by the base model indicate catch levels have been below the limits
¹⁶⁶ that would be associated with the Spawning Potential Ratio (SPR) = 50% limit (corre-
¹⁶⁷ sponding to a relative fishing intensity of 100%) (Table [d](#) and Figure [h](#)). SPR is calculated
¹⁶⁸ as the lifetime spawning potential per recruit at a given fishing level relative to the life-
¹⁶⁹ time spawning potential per recruit with no fishing. The relative inverse SPR over the last
¹⁷⁰ decade increased ranged from 0.64 to 0.77 from 2009-2015, and ranged from 0.80 to 0.82
¹⁷¹ from 2016-2018 (Table [d](#)).

Table d: Recent trend in spawning potential ratio (entered as $(1 - SPR)/(1 - SPR_{50\%})$) and exploitation for GBYR in the model.

Year	Estimated (1-SPR)/(1- SPR50%)	~ 95% confidence interval	Exploitation rate	95% confidence interval
2009	0.64	0.5 - 0.78	0.07	0.05 - 0.09
2010	0.78	0.64 - 0.93	0.10	0.08 - 0.13
2011	0.77	0.62 - 0.92	0.10	0.07 - 0.12
2012	0.67	0.52 - 0.81	0.07	0.05 - 0.09
2013	0.64	0.49 - 0.78	0.07	0.05 - 0.09
2014	0.74	0.59 - 0.88	0.09	0.06 - 0.11
2015	0.77	0.62 - 0.92	0.10	0.07 - 0.12
2016	0.81	0.66 - 0.96	0.10	0.07 - 0.13
2017	0.82	0.66 - 0.98	0.09	0.06 - 0.11
2018	0.80	0.63 - 0.96	0.07	0.05 - 0.1

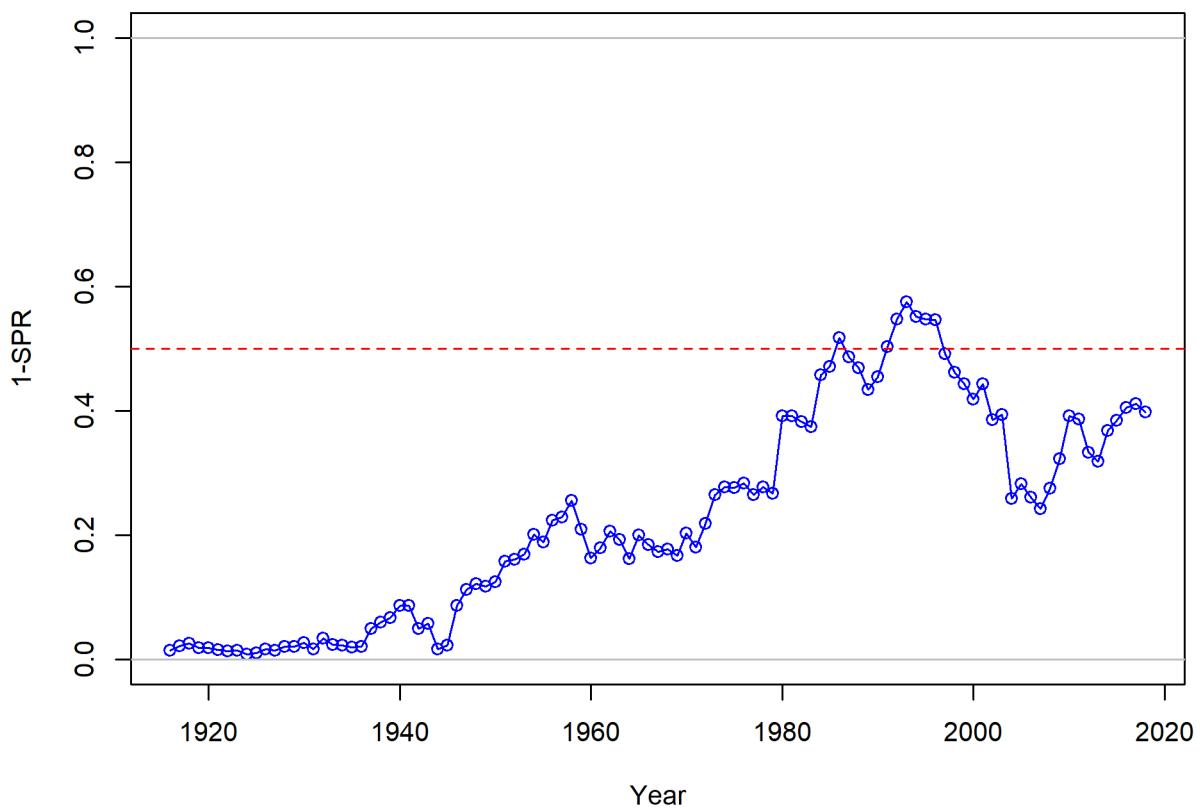

Figure h: Estimated inverse spawning potential ratio (SPR) for the post-STAR base model, plotted as one minus SPR so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the $\text{SPR}_{50\%}$ harvest rate. The last year in the time series is 2018. | [fig:SPR_all](#)

¹⁷² **Ecosystem Considerations**

ecosystem-considerations

- ¹⁷³ In this assessment, ecosystem considerations were not explicitly included in the analysis.
¹⁷⁴ This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)
¹⁷⁵ that could contribute ecosystem-related quantitative information for the assessment.

¹⁷⁶ **Reference Points**

reference-points

- ¹⁷⁷ This stock assessment estimates that GBYR in the model is above the biomass target
¹⁷⁸ ($SB_{40\%}$), and well above the minimum stock size threshold ($SB_{25\%}$). The estimated relative
¹⁷⁹ depletion level for the base model in 2018 is 0.439 (95% asymptotic interval: 0.341-0.536,
¹⁸⁰ corresponding to an unfished spawning biomass of 552 million eggs (95% asymptotic interval:
¹⁸¹ 337 - 767 million eggs) of spawning biomass in the base model (Table e). Unfished age 1+
¹⁸² biomass was estimated to be 2,042 mt in the base case model. The target spawning biomass
¹⁸³ ($SB_{40\%}$) is 504 million eggs, which corresponds with an equilibrium yield of 143 mt. Equi-
¹⁸⁴ librium yield at the proxy F_{MSY} harvest rate corresponding to $SPR_{50\%}$ is 134 mt (Figure
¹⁸⁵ i).

Table e: Summary of reference points and management quantities for the base case model.

Quantity	Estimate	tab:Ref_pts_mod1	
		Low	High
		2.5% limit	2.5% limit
Unfished spawning output (million eggs)	1,261	968	1,554
Unfished age 1+ biomass (mt)	2,042	1,637	2,448
Unfished recruitment (R_0)	3,125	2,643	3,606

Retained Catch MSY (mt)	163	141	185

186 Management Performance

management-performance

187 Gopher and black-and-yellow rockfishes are managed as part of the minor nearshore complex
 188 in the Pacific Coast Groundfish Fishery Management Plan. The total mortality of the
 189 minor nearshore rockfish has been below the ACL in all years (2011-2016). Total mortality
 190 estimates from the NWFSC are not yet available are not yet available for 2017-2018. GBYR
 191 total mortality was on average 20% of the total minor nearshore rockfish total mortality
 192 from 2011-2016. A summary of these values as well as other base case summary results can
 193 be found in Table f.

Table f: Recent trend in total mortality for gopher and black-and-yellow rockfishes (GBYR), combined, relative to the management guidelines for Nearshore Rockfish South of $40^{\circ}10' N.$ latitude. Total mortality estimates are based on annual reports from the NMFS NWFSC.

GBYR		Shallow Nearshore Rockfish South	<small>tab:mnmgt_perform</small>	
Year	Total mortality	Total mortality	ACL	OFL
2011	122.87	436	1,001	1,156
2012	91.96	445	1,001	1,145
2013	104.53	495	990	1,164
2014	103.63	596	990	1,160
2015	107.95	676	1,114	1,313
2016	111.55	641	1,006	1,288
2017	-	-	1,163	1,329
2018	-	-	1,179	1,344

194 Unresolved Problems and Major Uncertainties

unresolved-problems-and-major-uncertainties

195 The major source of uncertainty identified during the STAR panel is the structure of complex and contribution of each of the two species to the complex and biological parameters 196 differences. Additionally, there is currently no information for either species on regional 197 differences in biological parameters and contributions to the complex. 198

199 Decision Table

decision-table

200 The forecasts of stock abundance and yield were developed using the post-STAR base model, 201 with the forecasted projections of the OFL presented in Table [g](#). The total catches in 2019 202 and 2020 are set to the PFMC adopted ACL of 114 mt.

203 Uncertainty in the forecasts is based upon the three states of nature agreed upon at the 204 STAR panel and are based three states of nature of growth. The external estimates of 205 growth were different than the internal estimates. Given that natural mortality is fixed in 206 the post-STAR base model, and the growth parameter k is negatively correlated with natural 207 mortality, k was chosen as the axis of uncertainty. The high state of nature fixes k at the 208 external estimate, and the low state of nature is the same distance in log space from the 209 base as the high state of nature. The low state of nature fixed k at 0.46 and the L1 and L1 210 parameters are estimated at 14.1 and 30.6, respectively. The high state of nature fixes all 211 growth parameters, $k = 0.248$, L1 = 13.8, and L2 = 28.5 to the external estimate of growth. 212 The growth parameters in the base model were estimated as $k = 0.107$, L1 = 13.4, and L2 213 = 28.8.

214 The forecasted buffer ramp was calculated assuming a category 2 stock, with sigma = 1.0 215 and a $p^* = 0.45$. The buffer ranges from 0.874 in 2021 ramping to 0.803 in 2030. Current

medium-term forecasts based on the alternative states of nature project that the stock will remain above the target threshold of 40% for all but two scenarios (Table h). The low state of nature with the high catches results in a stock at 26.4% of unfished in 2030 and the base state model with the high catches results in a stock at 33.2% of unfished in 2030. The base case model with the base catches results in an increasing stock over the period from 2021-2030. If the growth of GBYR is slower than the base model suggests, but the base case catches are removed, the stock will be at the target threshold in 2030.

Table g: Projected OFL, default harvest control rule catch (ABC = ACL) above 40% SSB), biomass, and depletion using the post-STAR base case model with 2019-2020 catches set equal to the projected catch (114 mt) rather than the ABC.

Year	OFL (mt)	ABC Catch (mt)	Age 0+ Biomass (mt)	Spawning Output (million eggs)	Fraction unfished
2019	154	114	1281	552.5	43.8
2020	154	114	1292	558.3	44.3
2021	136	119	1291	578.2	45.9
2022	137	119	1296	601.1	47.7
2023	143	122	1300	621.5	49.3
2024	150	127	1302	633.3	50.2
2025	155	130	1300	636.2	50.5
2026	158	131	1295	632.6	50.2
2027	158	130	1290	626.0	49.7
2028	156	128	1286	619.4	49.1
2029	155	125	1284	614.8	48.8
2030	153	123	1283	612.7	48.6

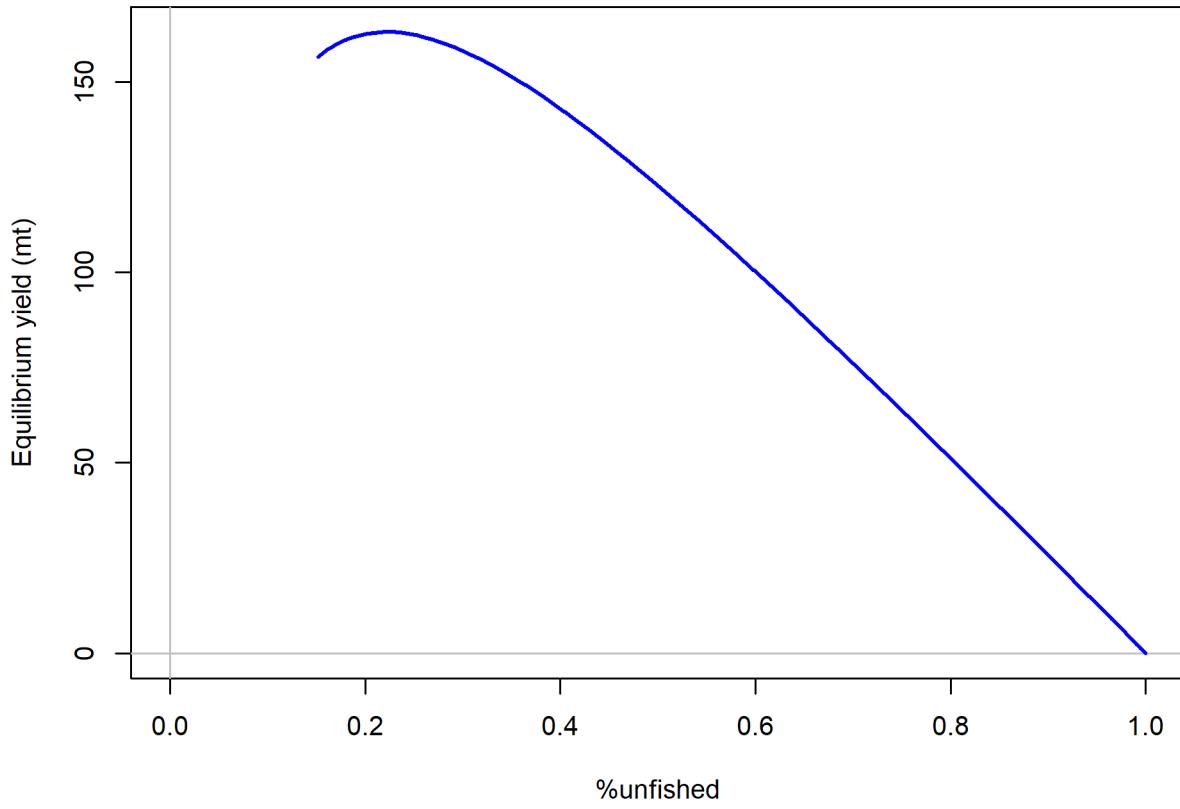

Figure i: Equilibrium yield curve for the base case model. Values are based on the 2018 fishery selectivity and with steepness fixed at 0.72. [fig:Yield_all](#)

Table h: Summary of 10-year projections beginning in 2020 for alternate states of nature based on an axis of uncertainty for the model. Columns range over low, mid, and high states of nature, and rows range over different assumptions of catch levels. The low state of nature fixed the growth parameter k at 0.046 and the high state fixes all growth parameters to the external estimate ($k = 0.248$, $L1 = 13.8$, $L2 = 28.5$)

		States of nature						
		Low State		Base State		High State

223 Research and Data Needs

research-and-data-needs

224 We recommend the following research be conducted before the next assessment:

- 225 1. Investigate structure of complex and contribution of each species to the complex and
226 biological parameters differences. Also, investigate regional differences within species.**
- 227 2. Structure of complex and contribution of each species to the complex and biological
228 parameters differences. Also regional differences within species.**
 - 229 (a) Life history studies**
 - 230 (b) Research to identify proportion of each species in population and in catch**
- 231 3. Historical catch reconstruction data, more so for the recreational fishery**
- 232 4. Refine PISCO survey and analysis to better identify age-0 in each month of survey,
233 which would benefit from occasional sampling later in the year to identify size at age-0.**
- 234 5. Refine CCFRP survey index and continue coastwide sampling.**
- 235 6. Recommend commercial and recreational data length and age collection.**
- 236 7. Integrating data collection across the different research needs to improve efficacy of
237 data collection.**
- 238 8. Environmental drivers/co-variates for biological parameters, particularly recruitment.**
- 239 9. Make recreational survey dockside (PR) data available at trip level because of differ-
240 ences in the selectivity.**
- 241 10. Resolve differences between CalCOM and PacFIN expanded length compositions.**

242 **1 Introduction**

introduction

243 **1.1 Basic Information and Life History**

basic-information-and-life-history

244 *Population Structure and Complex Assessment Considerations*

245 There have been a number of analyses conducted on the genetic differentiation between go-
246 pher rockfish and black-and-yellow rockfish. The studies have yielded a range of results,
247 but have generally concluded that there is unusually low genetic differentiation between the
248 two species. The most frequently used measure of genetic analyses to evaluate evidence for
249 population differentiation is the fixation index (F_{ST}), defined as the proportion of the total
250 genetic variation in one sub-population (subscript S) relative to the total genetic variation
251 (subscript T) (Hauser and Carvalho 2008, Waples et al. 2008). Values of F_{ST} range from
252 0 to 1 where a zero value implies the populations are panmictic and a value closer to one
253 implies the two populations are genetically independent. Values of F_{ST} thought to be consis-
254 tent with biologically meaningful genetic differentiation and demographic isolation between
255 populations range from 0.01 to 0.05 (Waples and Gaggiotti 2006). It is also important to
256 note that F_{ST} values are dependent on the study's sample size and it may not necessarily be
257 appropriate to compare them across studies.

258 Morphologically, gopher and black-and-yellow rockfishes are almost indistinct, except for
259 their color variation (Hubbs and Schultz 1933). Early efforts to evaluate whether the two
260 species were genetically distinct began with an allozyme analysis by Seeb et al. (1986),
261 which did not detect genetic differentiation between gopher and black-and-yellow rockfish.
262 However, as allozymes are proteins that are often conserved, this early work was not neces-
263 sarily representative of genome-wide relationships between the two groups. In a subsequent
264 study of restriction site polymorphisms, Hunter et al. (1994) found slight but significant
265 differences between species based on restriction fragment length polymorphisms (RFLP's).
266 Following that study, an analysis of the mitochondrial control region by Alesandrini and
267 Bernardi (1999) did not detect differences between the two species, although mtDNA also
268 has limitations regarding how results can be extrapolated across the nuclear genome. Anal-
269 ysis of seven microsatellite loci by Narum et al. (2004) found an F_{ST} of 0.049 across the
270 overlapping range of the two species, which provided some evidence of divergence, although
271 such divergence is relatively low compared to other species within *Sebastes*. Those authors
272 characterized their results as suggesting that the two are “reproductively isolated incipient
273 species.” Buonaccorsi et al. (2011) found an even lower F_{ST} of 0.01 using 25 microsatellite
274 loci, and concluded that gopher and black-and-yellow rockfish “have not completed the spe-
275 ciation process.” All of these studies are indicative of low levels of genetic divergence and a
276 high probability of ongoing gene flow between the two nominal species.

277 Most recently, an analysis of rockfish species assignment using microhaplotypes by Baetscher
278 (2019) observed mistaken genetic assignment of a small number of individuals between go-
279 pher and black-and-yellow rockfishes, while no other species among the 54 rockfishes analyzed

resulted in mis-assignments. In addition, comparisons of F_{ST} values within the study indicated that the level of genetic differentiation observed between gopher and black-and-yellow rockfishes is lower ($F_{ST} = 0.015$) than that observed among all other pairwise comparisons of the 54 species in the *Sebastodes* genus that were included in their analysis. Baetscher (2019) characterized the results as suggestive of the two species representing “sister species with evidence of ongoing gene flow,” noting that a more rigorous evaluation of the level of genetic distinction between these two species would benefit from whole-genome sequencing of representatives from each species group.

In addition to the differences in coloration, the depth distribution and range differ between the two species. The range of both species extends from Cape Blanco Oregon to Baja California. Both species are uncommon north of Fort Bragg, California and black-and-yellow rockfish is uncommon south of Point Conception, California. However, gopher rockfish can be found as far south as Punta San Roque on the Baja peninsula. Gopher rockfish are found in rocky reef habitat from the intertidal to depths of 264 ft (80 m) with a predominant depth distribution of 30 to 120 ft (9-37 m), while the black-and-yellow rockfish occupies depths from the intertidal to 120 ft (40 m) and is predominantly observed in depths shallower than 60 ft (18 m) (Eschmeyer et al. 1983, Love et al. 2002).

Both species are solitary, sedentary, and territorial with home ranges of 10-12 square meters (Love et al. 2002). A large percentage (67-71%) of black-and-yellow rockfish returned to the site of capture within two weeks after translocated within 50 m (Hallacher 1984). Lea et al. (1999) found that gopher rockfish exhibit minor patterns of movement (<12.8 km) with all fish being recaptured on the same reef system where they were tagged. Matthews (1985) found that 11.8% of tagged and recaptured gopher rockfish, and 25% of black-and-yellow rockfish, moved from four low-relief natural reefs to a new high-relief artificial reef in Monterey Bay. The maximum distance between the natural and artificial reefs traveled by gopher or black-and-yellow rockfish was 1.6 km. After only a year, the fish assemblage on the artificial reef closely resembled that of the nearby natural reefs. The paper did not address the spatial segregation of gopher and black-and-yellow rockfish on the new artificial reef.

Larson (1980) conducted a study on the territoriality and segregation between gopher and black-and-yellow rockfishes. When one species was removed, the other extended its depth range to areas where the other previously occupied, indicating inter-specific competition plays a role in controlling their depth distributions where both species are present. Of the two species, black-and-yellow rockfish are socially dominant and aggressive towards excluding gopher rockfish from shallower waters.

Both species feed at night, with similar diets composed primarily of crabs and shrimp, supplemented by fish and cephalopods (Larson 1972, 1985, Love et al. 2002). Loury et al. (2015) found no significant differences in the diet of gopher rockfish inside and outside the 35 year old Point Lobos Marine Protected Area (MPA). She did find the diet of gopher rockfish at Año Nuevo (shallower and north of Point Lobos) was dominated by crabs and dominated by brittle stars at southern, deeper study locations. Zuercher (2019) examined the diets of

321 a suite of nearshore rockfish species including black-and-yellow and found that they relied
322 on hard-bodied benthic invertebrates such as Brachyuran crabs, shrimps, other arthropods,
323 and octopus. The diet of black-and-yellow rockfish remained the same across sampling years,
324 but they occupied a lower trophic level during the upwelling season.

325 1.2 Early Life History

early-life-history

326 Gopher and black-and-yellow rockfish have similar juvenile development. Both rockfish
327 species are viviparous and release one brood per season between January and July (Echev-
328 erria 1987). Larvae are approximately 4 mm in length at birth and have a 1-2 month pelagic
329 stage before recruiting to the kelp forest canopy, i.e., surface fronds of *Macrosystis pyrifera*
330 and *Cystoseira osmundacea* at around 15-21 mm (Anderson 1983, Wilson et al. 2008).
331 The larvae are transparent until they reach juvenile stage at 22-23 mm. Differences in col-
332 oration between the two species begin to occur at 25-30 mm and can be used to identify one
333 species from the other. Gopher rockfish become more orange and brown, while black-and-
334 yellow rockfish become more black and yellow. Benthic juveniles associate with *Macrosystis*
335 holdfasts and sporophylls (Anderson 1983).

336 The juveniles undergo ontogenetic migration down the stalks to deeper depths, finally settling
337 on rocky reef habitat in their respective adult depth distribution. Juvenile bocaccio and other
338 fish predate on young of year and other reef dwelling species including cabezon predate on
339 post-settlement juveniles. Individuals avoid rough surge conditions and predators by hiding
340 in the rocky bottom during the daylight hours, then returning to more open water at dusk
341 (Love et al. 2002).

342 1.3 Map

map

343 A map showing the scope of the assessment and depicting boundaries at Cape Mendocino
344 to the north and the U.S./ Mexico border at the south (Figure 1). The recreational fishing
345 fleet was split into two fleets at Point Conception.

346 1.4 Ecosystem Considerations

ecosystem-considerations-1

347 In this assessment, ecosystem considerations were not explicitly included in the analysis.
348 This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)
349 that could contribute ecosystem-related quantitative information for the assessment.

350 1.5 Fishery Information

fishery-information

351 The hook-and-line fishery off California developed in the late 19th century (Love et al. 2002).
352 The rockfish trawl fishery was established in the early 1940s, when the United States became
353 involved in World War II and wartime shortage of red meat created an increased demand
354 for other sources of protein (Harry and Morgan 1961, Alverson et al. 1964).

355 Gopher and black-and-yellow (referred to from hereon as GBYR when discussing the com-
356 plex) rockfish have been a minor component of the commercial and recreational rockfish
357 fishery since at least the late 1960s (CFIS and RecFIN). The commercial catch histories
358 of the two species cannot easily be separated (Figure 2). From 1916-1936 only black-and-
359 yellow rockfish were reported in the landings, and an average of 0.04 mt of black-and-yellow
360 rockfish are reported from 1937-1983. Black-and-yellow rockfish reappear in the landings in
361 1984 with 7.2 mt landed commercially. From 1985-1988 the trend switches and only black-
362 and-yellow rockfish appear in the commercial landings, with gopher rockfish averaging 0.1
363 mt landed, and 0 mt reported in 1987. From 1988 and on, the landings are dominated by
364 gopher rockfish, and both species are represented in the commercial landings.

365 The landings from south of Point Conception are minor throughout the time period, with
366 peaks in the 1950s and 60s for gopher rockfish. Black-and-yellow rockfish are rare south of
367 Point Conception and expected that these catches are minimal.

368 The live fish fishery began in the early 1990s, with the first reported commercial landings of
369 live gopher rockfish in 1993, and black-and-yellow rockfish a year later. By 1995 over half
370 (57%; 39 mt) of the commercial landings were from the live fish fishery. This increased quickly
371 over the next few years and has been on average 84% of the landed gopher and black-and-
372 yellow rockfish (also referred to GBYR to reference the complex in this assessment) since
373 2000. The majority of the landings are from gopher rockfish north of Point Conception.
374 Landings of live GBYR south of Point Conception were higher in the late 1990s, (max. 3.2
375 mt in 1999), and have been averaging 0.4 mt since 2003.

376 The ex-vessel value of GBYR increased from less than \$40,000 in 1984 and peaked at \$680,452
377 in 1996 (Figure 3). The ex-vessel revenue has been fairly stable at around \$500,000 a year
378 since 2007. Prior to the live fish fishery in 1994, the average price per pound for either
379 species was around \$2 a pound. The live fish fishery increased the value of both species to
380 an average of \$6-\$8 a pound. The maximum reported value of either a gopher or black-and-
381 yellow rockfish was \$20 a pound in 2003.

382 The recreational GBYR fishery for California is most prominent north of Point Conception
383 throughout the entire catch history (Figure a). The recreational landings increased from
384 1928 to 1980. The sharp increase in the 1980s could be an artifact of the MRFSS sampling
385 program that began in 1980; however, the more recent recreational landings also exhibit a
386 cyclical trend of years with high catches followed by period of decreased recreational landings.
387 The CRFS era recreational total mortality represents the most accurate description of the
388 recreational fleet's catches in terms of area, mode and species (Figure 4).

389 Recreational GBYR catches are dominated by gopher rockfish north of Point Conception in
390 the private/rental (PR) and party/charter (PC or CPFV) modes. South of Point Conception
391 gopher rockfish are predominately caught by the CPFV fleet, with all other modes being
392 insignificant. The total recreational mortality of black-and-yellow rockfish south of Point
393 Conception since 2005 is 3 mt, compared to 106 mt north of Point Conception. The total
394 mortality since 2005 for gopher rockfish is 86 mt south of Point Conception and 669 mt north
395 of Point Conception.

396 1.6 Summary of Management History

summary-of-management-history

397 Prior to the adoption of the Pacific Coast Groundfish Fishery Management Plan (FMP)
398 in 1982, GBYR were managed through a regulatory process that included the California
399 Department of Fish and Wildlife (CDFW) along with either the California State Legislature
400 or the Fish and Game Commission (FGC) depending on the sector (recreation or commercial)
401 and fishery. With implementation of the Pacific Coast Groundfish FMP, GBYR came under
402 the management authority of the Pacific Fishery Management Council (PFMC), and were
403 managed as part of the *Sebastodes* complex. Because neither species had undergone rigorous
404 stock assessment and did not compose a large fraction of the landings they were classified
405 and managed as part of “Remaining Rockfish” under the larger heading of “Other Rockfish”
406 (PFMC ([2002, 2004](#))).

407 Since the early 1980s a number of federal regulatory measures have been used to manage
408 the commercial rockfish fishery including cumulative trip limits (generally for two- month
409 periods) and seasons. Starting in 1994 the commercial groundfish fishery sector was divided
410 into two components: limited entry and open access with specific regulations designed for
411 each component. Other regulatory actions for the general rockfish categories have included
412 area closures, gear restrictions, and cumulative bimonthly trip limits set for the four different
413 commercial sectors - limited entry fixed gear, limited entry trawl, open access trawl, and open
414 access non-trawl. Harvest guidelines are also used to regulate the annual harvest for both
415 the recreational and commercial sectors.

416 In 2000, changes in the PFMC’s rockfish management structure resulted in the discontinued
417 use of the *Sebastodes* complex, and was replaced with three species groups: nearshore, shelf,
418 and slope rockfishes (January 4, 2000; 65 FR 221), of which GBYR are included in the
419 nearshore group. Within the nearshore group, they are included in the “shallow nearshore
420 rockfish” component.

421 During the late 1990s and early 2000s, major changes also occurred in the way that California
422 managed its nearshore fishery. The Marine Life Management Act (MLMA), which was passed
423 in 1998 by the California Legislature and enacted in 1999, required that the FGC adopt an
424 FMP for nearshore finfish ([Wilson-Vandenberg et al. 2014](#)). It also gave authority to the
425 FGC to regulate commercial and recreational nearshore fisheries through FMPs and provided
426 broad authority to adopt regulations for the nearshore fishery during the time prior to

427 adoption of the nearshore finfish FMP. Within this legislation, the Legislature also included
428 commercial size limits for ten nearshore species including GBYR (10-inch minimum size)
429 and a requirement that commercial fishermen landing these ten nearshore species possess a
430 nearshore permit.

431 Following adoption of the Nearshore FMP and accompanying regulations by the FGC in fall
432 of 2002, the FGC adopted regulations in November 2002 which established a set of marine
433 reserves around the Channel Islands in southern California (which became effective April
434 2003). The FGC also adopted a nearshore restricted access program in December 2002
435 (which included the establishment of a Deeper Nearshore Permit) to be effective starting in
436 the 2003 fishing year.

437 Also, since the enactment of the MLMA, the Council and State in a coordinated effort
438 developed and adopted various management specifications to keep harvest within the harvest
439 targets, including seasonal and area closures (e.g. the CCAs; a closure of Cordell Banks
440 to specific fishing), depth restrictions, minimum size limits, and bag limits to regulate the
441 recreational fishery and license and permit regulations, finfish trap permits, gear restrictions,
442 seasonal and area closures (e.g. the RCAs and CCAs; a closure of Cordell Banks to specific
443 fishing), depth restrictions, trip limits, and minimum size limits to regulate the commercial
444 fishery.

445 The state of California has adopted regulatory measures to manage the fishery based on
446 the harvest guidelines set forth by the PFMC. The commercial open access and limited
447 entry fixed gear sectors have undergone three different spatial management changes since
448 2000. Since 2005, both have managed the area south of 40°10' N. latitude as one area. The
449 open access commercial fishery is managed based on bimonthly allowable catches, that have
450 ranged from 200 pounds to 1800 pounds per two months since 2000. From 2005 to 2018, the
451 catch limits have doubled and are now set at 1200 pounds per two months (for all months)
452 with March and April remaining closed. The limited entry fixed gear sector has followed the
453 same pattern as the open access sector with bi-monthly limits and a doubling of the catch
454 since 2005. The limited entry trawl fleet is managed on monthly limits on an annual basis.
455 Since 2011, the limit has been 300 pounds per month for non-IFQ species. A history of
456 California's commercial regulations from 2000-2018 can be found in [Appendix A](#). A 10-inch
457 total length minimum size limit was implemented in 1999 for both species in the commercial
458 fleet.

459 Significant regulatory changes in California's recreational sector began with a change from
460 unlimited number of hooks and lines allowed prior to 2000 to no more than three hooks and
461 one line per angler in 2000. Since 2001, the limit has been no more than two hooks and one
462 line per angler. There is no size limit in the recreational fishery for gopher or black-and-
463 yellow rockfish. A nearshore complex sub-bag limit that included GBYR was in place from
464 1999 to 2005, but was eliminated thereafter.

465 California also began spatial management, including area closures, and depth restrictions for
466 the recreational fleet in 2000. In general, the recreational season north of Point Conception

467 extends from April to December, and south of Point Conception from March to December.
468 In the area that GBYR are most commonly landed, from Monterey to Morro Bay, the depth
469 restrictions have been between 30 and 40 fathoms until 2017. In 2017 the depth restrictions
470 were eased by 10 fathoms, opening up fishing depths along the central California coast
471 that had not been open consistently since 2002. In both 2017 and 2018, the deepest 10
472 fathoms was closed prior to the season in December due to high by-catch rates of yelloweye
473 rockfish, one of two rockfish species that are still overfished. A full history of the recreational
474 regulations relating to the spatial management of the fleet can be found in [Appendix B](#).

475 1.7 Management Performance

management-performance-1

476 The contribution of GBYR to the nearshore rockfish OFLs is currently derived from two
477 sources: 1) forecasts from Key et al. ([2005](#)), from Cape Mendocino to Point Conception,
478 and 2) a Depletion Corrected Average Catch (DCAC (MacCall [2009](#))) for the area south
479 of Point Conception. The total mortality of the nearshore rockfish south complex has been
480 below the ACL in all years (2011-2016). Total mortality estimates from the NWFSC are
481 not yet available for 2017-2018. GBYR total mortality was on average 20% of the total
482 nearshore rockfish south total mortality from 2011-2016. The recent GBYR total mortality
483 contributed approximately 9% to the nearshore rockfish south OFL, and GBYR catches have
484 not exceeded the GBYR OFLs in recent years. GBYR is a small component of the nearshore
485 rockfish south complex that includes twelve other species. A summary of these values as
486 well as other post-STAR base model summary results can be found in Table [f](#).

487 1.8 Fisheries Off Mexico or Canada

fisheries-off-mexico-or-canada

488 The range of GBYR does not extend north to the Canadian border, and they are rarely
489 encountered in Oregon and Washington. The southern end of the gopher rockfish's range
490 extends to Punta San Roque (southern Baja California) while the southern end of the black-
491 and-yellow rockfish's range extends to Isla Natividad (central Baja California) (Love et al.
492 [2002](#)). However, black-and-yellow rockfish are rare south of Point Conception, California.
493 This was no available information on the fishery for GBYR at the time of this assessment,
494 nor additional details on the abundance or distribution patterns in Mexican waters.

495 2 Assessment

assessment

496 2.1 Data

data

497 Data used in the GBYR assessment are summarized in Figure [5](#). Descriptions of the data
498 sources are in the following sections.

499 **2.1.1 Commercial Fishery Landings**

commercial-fishery-landings

500 *Overview of gopher and black-and-yellow catch history*

501 Commercial fishery landings for gopher and black-and-yellow rockfishes have not been re-
502 ported consistently by species throughout the available catch history (Figure 2). The period
503 from 1916-1935 indicates that only black-and-yellow rockfish were landed in the commercial
504 fishery, which then switched to predominately gopher rockfish from 1937-1984. From 1985-
505 1988 the landings data suggest that only black-and-yellow rockfish were landed and not until
506 1995 are both species well-represented in the catches. Pearson et al. (2008) noted:

507 The fact that the majority of estimated landings are not based on actual sam-
508 pling, combined with the likelihood for misidentification [between gopher and
509 black-and-yellow rockfishes], suggests that our landing estimates are generally
510 unreliable [see Figure 37 in Pearson et al. (2008)]. This is particularly true for
511 the time interval between 1983 and 1988. Between 1983 and 1988, market cat-
512 egory 962 (group gopher) landings increased sharply while market category 263
513 (gopher rockfish) landings declined (not visible in Figure 37 since the stratum
514 was unsampled and the landings were converted to unspecified rockfish). Port
515 samples indicated a shift from gopher rockfish to black-and-yellow rockfish during
516 the same time interval, suggesting problems with identification. We suggest that
517 if black-and-yellow landings are combined with gopher landings, the estimates
518 would be generally reliable for the group.

519 There is no way to tease apart the historical catches by species and even across north and
520 south of Point Conception prior to about 1995. This precludes the ability to model the catch
521 histories for either species accurately. Given these constraints, all commercial data were
522 combined to represent one commercial fleet in the assessment. Additional details regarding
523 this decision are described below.

524 The stock assessment of gopher rockfish in 2005 did not explicitly include black-and-yellow
525 rockfish landings. A comparison of the recreational and commercial landings from the 2005
526 assessment to those used in this assessment suggest the 2005 assessment may have included
527 some black-and-yellow rockfish landings (Figure 6). The 2005 assessment estimated recre-
528 ational landings from 1969-1980 based on a ratio of commercial to recreational landings,
529 whereas this assessment makes use of the California Catch Reconstruction landings esti-
530 mates (Ralston et al. 2010).

531 *Commercial Landings Data Sources*

532 The California Catch Reconstruction (Ralston et al. 2010) contains landings estimates of
533 commercial landings from 1916-1968 and was queried on 4 April 2019 for GBYR. There were
534 no estimated gopher rockfish landings prior to 1937. Landings in this database are divided

535 into trawl and ‘non-trawl.’ Since the majority of GBYR are caught in the commercial fixed
536 gear fisheries, only estimated catch in the ‘non-trawl’ was used. A total of 0.154 mt (3.18%)
537 were removed from Eureka commercial landings (based on current proportions of commercial
538 catch from north of Cape Mendocino in Eureka) since the assessment represents the GBYR
539 stock south of Cape Mendocino. The majority of GBYR commercial landings (avg. 83%)
540 are landed in the Monterey and Morro Bay port complexes.

541 Contemporary landings were extracted from two data sources, the California Cooperative
542 Groundfish Survey, [CALCOM](#)) and the Pacific Fisheries Information Network ([PacFIN](#))
543 landings database. Both databases are based on the same data sources (CALCOM landing
544 receipts), but apply a catch expansion based on different algorithms. CALCOM collects
545 information including species composition data (i.e. the proportion of species landed in a
546 sampling stratum), and landing receipts (sometimes called “fish tickets”) that are a record
547 of pounds landed in a given stratum. Strata in California are defined by market category,
548 year, quarter, gear group, port complex, and disposition (live or dead). Although many
549 market categories are named after actual species, catch in a given market category can
550 consist of several species. These data form the basis for the “expanded” landings, i.e.,
551 species composition data collected by port samplers were used to allocate pounds recorded
552 on landing receipts to species starting in 1978. Use of the “Gopher Rockfish” or the “Black-
553 and-Yellow Rockfish” categories alone to represent actual landings of GBY would not be
554 accurate.

555 See Pearson et al. Appendix C ([2008](#)) for a simple example of the expansion calculations
556 for the CALCOM database and a description of the landings in PacFIN can be found in
557 Sampson and Crone ([1997](#)). Both databases, including species compositions, and expanded
558 landings estimates are stored at the Pacific States Marine Fisheries Commission, a central
559 repository of commercial landings data for the U.S. West Coast. As a note, CALCOM is the
560 only source for landings from 1969-1980.

561 Commercial landings from 1981-2018 were queried for a final time from the CALCOM
562 database on 4 April 2019 and from PacFIN on 3 June 2019. There are very small dif-
563 ferences in commercial landings between CALCOM and PacFIN from 1981-2018 (Figure 7).
564 Landings estimates from PacFIN were used in the assessment (Table 1). Landings were
565 stratified by year, quarter, live/dead, market category, gear group, port complex, and source
566 of species composition data (actual port samples, borrowed samples, or assumed nominal
567 market category). Data from individual quarters were aggregated at the year level. Fish
568 landed live or dead were combined, due to changes over time in the reliability of condi-
569 tion information (Don Pearson, retired NMFS SWFSC, personal communication). From
570 1916-1968, on average, 74% of GBYR were landed north of Point Conception, which rose to
571 97% from 1978-2018. Given the smaller landings south of Point Conception and the similar
572 length composition of GBYR north and south of Point Conception, no spatial separation
573 was considered for the commercial fleet.

574 **2.1.2 Commercial Discards**

commercial-discards

575 The West Coast Groundfish Observer Program (WCGOP) provides observer data on dis-
576 carding across fishery sectors back to 2003. Gopher and black-and-yellow rockfishes have
577 species-specific depth-stratified commercial fishery discard mortality rates (Pacific Fishery
578 Management Council 2018). In consultation with WCGOP staff, the STAT used estimates of
579 total discard mortality from WCGOP's Groundfish Expanded Mortality Multiyear (GEMM)
580 report. WCGOP observes between 1-5% of nearshore fixed gear landings annually south of
581 40°10' N. latitude (coverage rates available [here](#)). The expanded estimates of total discard
582 weight by species is calculated as the ratio of the observed discard weight of the individual
583 species divided by the observed landed weight from PacFIN landing receipts. WCGOP disc-
584 card estimates for the nearshore fixed gear fishery take into account the depth distribution
585 of landings in order to appropriately apply the depth-stratified discard mortality rates by
586 species (Somers et al. 2018). The discard mortality for 2018 was estimated as an average
587 of the discard mortality from 2013-2017. Discard mortality was estimated from the period
588 prior to WCGOP discard estimates (1916-2002) based on the average discard mortality rate
589 from 2003-2016 (2017 was excluded because 2017 discard mortality was disproportionately
590 higher than all other years) (Table 1).

591 **2.1.3 Commercial Fishery Length and Age Data**

commercial-fishery-length-and-age-data

592 Biological data from the commercial fisheries that caught GBYR were extracted from CAL-
593 COM on 9 May 2019. The CALCOM length composition data were catch-weighted to
594 “expanded” length the raw length composition data (Table 2). The 2005 assessment used
595 commercial length composition information from CALCOM, but did not include black-and-
596 yellow rockfish and is not directly comparable. The 2005 assessment used 2 cm length bins
597 from 16-40 cm, where this assessment uses 1 cm length bins from 4-40 cm. Sex was not
598 available for the majority (99.5%) of the commercial length, and the assessment did not
599 find sexual dimorphism in growth for either species. We aggregated the commercial length
600 composition among all gears and regions south of Cape Mendocino.

601 Discard length compositions from WCGOP (2003-2017) were expanded based on the discard
602 estimates and were aggregated for all regions south of Cape Mendocino and across all fixed
603 gear fisheries.

604 A total of 46 ages were available for gopher rockfish from the commercial fisheries 2009-2011,
605 2016, and 2018. Though sparse, the data were included as conditional age-at-length for the
606 commercial fleet.

607 The input sample sizes for commercial length composition data were calculated via the
608 Stewart Method for fisheries (Ian Stewart, personal communication, IPHC, and developed at
609 NWFSC):

610 Input effN = $N_{\text{trips}} + 0.138 * N_{\text{fish}}$ if $N_{\text{fish}}/N_{\text{trips}}$ is < 44

611 Input effN = $7.06 * N_{\text{trips}}$ if $N_{\text{fish}}/N_{\text{trips}}$ is ≥ 44

612 Commercial length composition data are made available from PacFIN and the expanded
613 catch-weight length compositions were provided by Andi Stephens (NWFSC) processed
614 through the [PacFIN Utilities](#) package. We compared differences between the catch-weighted
615 length composition expansions from CALCOM and PacFIN. We were unable to reconcile the
616 difference between the two data sets. Sample sizes became more similar if the PacFIN data
617 were restricted to the same market categories used by CALCOM in the expansion. However,
618 both data sets apply other filters that we did not have time to explore. For instance, in the
619 year 2000, 290 more fish were used in the CALCOM expansion than in PacFIN, but in 2002,
620 150 more fish were used in the PacFIN expansions that were not used in CALCOM. Given
621 these caveats, Figure 8 shows the percent difference in the expanded length comps within a
622 year. The biggest difference is in length bin 32 in 2006. However, the same number of fish
623 and samples were used to expand the 2006 lengths in both databases, indicating there are
624 also fundamental differences in how the data are treated. Full documentation is not available
625 for the PacFIN length composition expansion program. Consequently the STAT chose to use
626 a query that they could completely understand and selectively develop from the CALCOM
627 database for the base model, although a sensitivity was conducted using the PacFIN-derived
628 length composition data.

629 **2.1.4 Recreational Fishery Landings and Discards**

[recreational-fishery-landings-and-discards](#)

630 *Historical recreational landings and discards, 1928-1980*

631 Ralston et al. (2010) reconstructed estimates of recreational rockfish landings and discards
632 in California, 1928-1980. Reported landings of total rockfish were allocated to species based
633 on several sources of species composition data. Estimates of GBYR landings and discards
634 (combined) from 1928-1979 are available from the SWFSC. For this assessment, historical
635 recreational catch was stratified by year and area (north and south of Point Conception).
636 The catches of GBYR reported in Ralston et al. (2010) are higher by an order of magnitude
637 than expected given the more recent catches of GBYR in the MRFSS and CRFS eras south
638 of Point Conception (Figure 9). The recreational catches estimated by Ralston et al. (2010)
639 were discussed with the paper's co-authors and also Commercial Passenger Fishing Vessel
640 (CPFV), i.e., party/charter mode, captains in California. A consensus was reached that
641 the estimated landings did not accurately represent the historical GBYR landings and an
642 alternative catch stream should be developed. One possibility for the inflated catches of
643 GBYR in southern California is that all nearshore shallow species were combined and a
644 constant relative fraction between the two was used to assign catches to each combination of
645 CDFW fishing block and year. The fraction of GBYR within the nearshore shallow species
646 group was likely overestimated.

647 The California Catch Reconstruction applied a linear ramp from 1928-1936 that was not
648 altered in this assessment. From 1937-1979 a linear ramp was developed from the 1936
649 estimate to the average recreational landing from 1980 and 1983 (1981-1982 catches inter-
650 polated as described in the next section) of 4.3 mt. The recreational catches north of Point
651 Conception were not altered from the original catch reconstruction. The resulting alternate
652 recreational catch streams are in (Table 3 and Figure 10).

653 The total difference in the catch streams from Figure 9 and Figure 10 is plotted in Figure
654 11. The differences in the catches are due to the addition of commercial discards prior to
655 2004 and the reduction of the recreational catches south of Point Conception.

656 *Marine Recreational Fisheries Statistics Survey (MRFSS), 1980-2003*

657 From 1980-2003, the Marine Recreational Fisheries Statistics Survey (MRFSS) executed a
658 dockside (angler intercept) sampling program in Washington, Oregon, and California (see
659 Holliday et al. (1984) for a description of methods). Data from this survey are available from
660 the Recreational Fisheries Information Network [RecFIN](#). RecFIN serves as a repository for
661 recreational fishery data for California, Oregon, and Washington. Catch estimates for years
662 1980-2003 were downloaded on 23 March 2019, and are consistent from 1992-2004 with the
663 previous assessment (Key et al. 2005) (Figure 6).

664 MRFSS-era recreational removals for California were estimated for two regions: north and
665 south of Point Conception. No finer-scale estimates of landings are available for this period.
666 Catches were downloaded in numbers and weight. Catch in weight is sometimes missing
667 from the database due to missing average weight estimates. We estimated average weights
668 based on adjacent strata as needed, although the effect was relatively minor (7.4 mt over all
669 years for gopher rockfish and 0.6 mt for black-and-yellow rockfish). Data were not available
670 for the CPFVs in Northern California from 1980-1982, and we used the average value from
671 this mode and region from 1983-1987 for these three years. MRFSS sampling was temporar-
672 ily suspended from 1990-1992, and we used linear interpolation to fill the missing years.
673 Sampling of CPFVs in Northern California was further delayed, and the linear interpolation
674 spans the period 1990-1995 for this boat mode and region. Landings data for the shore-
675 based modes (beach/bank, man-made/jetty and shore) were sparse throughout the MRFSS
676 sampling. All three shore-based modes were combined by region and linear interpolations
677 were applied missing data in 1981 for the Northern California and 1995, 1996-2001, and 2004
678 in Southern California.

679 Catches from north of Cape Mendocino were removed based on a CRFS-era average of frac-
680 tion of recreational landings north of Cape Mendocino by mode (3.3% of shore-based, 0.1% of
681 CPFV, and 0.2% of private/rental were removed). From 1980-1989, San Luis Obispo County
682 was sampled as part of Southern California (personal observation from MRFSS Type 3 sam-
683 pler examined catch where county is available for 1980-2004). This assessment separates the
684 recreational fleet at Point Conception. Recreational landings were re-allocated from southern
685 California from 1980-1992 by fleet based on the average proportion of recreational landings
686 in northern California from 1996-2004 (after sampling of the CPFV fleet in northern Cali-
687 fornia resumed). The average proportion re-allocated from southern to northern California

for the CPFV mode was 85%, 97% for the private/rental mode, and 81% for the shore-based modes. Data were pooled over all years and modes to estimate the landings re-allocation for the shore-based modes. Total recreational landings for 1981 and 1982 were 18.8 mt and 18.6 mt, respectively. These landings were >60 mt lower than any of the neighboring years. Landings from 1981-1982 were interpolated from the 1980 and 1983 landings.

Onboard sampling of the CPFV fleet began in 1999. A sampler rides along during a CPFV trip and records the catch from a subset of anglers onboard the vessel at each fishing location. Effort data are also recorded, allowing for CPUE calculations at a fine spatial resolution.

California Recreational Fisheries Survey (CRFS), 2004-2016

MRFSS was replaced with the California Recreational Fisheries Survey (CRFS) beginning January 1, 2004. Among other improvements to MRFSS, CRFS provides higher sampling intensity, finer spatial resolution (6 districts vs. 2 regions), and continued onboard CPFV sampling. Estimates of catch from 2004-2018 were downloaded from the RecFIN database a final time on 4 June 2019. We queried and aggregated CRFS data to match the structure of the MRFSS data, by year, and region (Table 3). Catches in the shore-based modes are small compared to the CPFV and private rental modes. All modes are combined, but separated at Point Conception for two recreational fleets in this assessment, just as was done for the California Catch Reconstruction and MRFSS time series.

Recreational Discards

Recreational discards were only added to the California Catch Reconstruction landings, as Ralston et al. (2010) did not address discards for the recreational reconstruction. Recreational removals from the California Department of Fish and Wildlife MRFSS era (1980-2003) includes catch type A + B1. Catch type A refers to estimates of catch based on sampler-examined catch. Catch type B1 includes mainly angler-reported discard, but also angler-reported retained fish that were unavailable to the sampler during the interview (e.g., fillets). The CRFS era removals account for depth-stratified discard mortality rate and the catch time series includes both retained and discarded catch (total mortality). We calculated the ratio of dead discards to total mortality from the CRFS era by region and mode. The region average across modes was applied to the California Catch Reconstruction as a constant. The result added 4.68% annually to recreational removals north of Point Conception and 4.05% annually to the removals South of Point Conception). The final time series of landings and discard mortality are in Table 3.

2.1.5 Recreational Fishery Length and Age Data

recreational-fishery-length-and-age-data

Recreational length composition samples for California were obtained from several sources, depending on the time period and boat mode (Table 2). This assessment makes use of a much longer time series of length composition data, relative to the previous assessment, as

724 described below. Input sample sizes for recreational length composition data were based on
725 the number of observed trips, when available. Other proxies that were used to estimate the
726 number of trips are described below.

727 There were no standardized coastwide surveys measuring retained or discarded fish from the
728 recreational fleet prior to 1980.

729 *CPFV length composition data, 1959-1978*

730 The earliest available length data for this assessment were described by Karpov et al. (1995),
731 who assembled a time series (1959-1972) of available California CPFV length data (made
732 available courtesy of W. Van Buskirk). For GBYR, data from 1959-1961 and 1966 were
733 available north of Point Conception and from 1959-1961 from south of Pt Conception. A
734 total of 716 (680 north of Point Conception) unsexed measurements of retained fish (no
735 discards) were included in the assessment (Table 2). Sampling of these length data did not
736 follow a consistent protocol over time and areas (data are unweighted), and therefore may
737 not be representative of total catch. Since the number of trips sampled was not reported
738 by Karpov et al. (1995), we assume the number of sampled trips is proportional to the
739 number of measured fish in each year, and estimated the number of trips using the ratio of
740 fish measured per trip in the MRFSS data (roughly 10 fish per trip).

741 Collins and Crooke (n.d.) conducted an onboard observer survey of the CPFV fleet in
742 southern California from 1975-1978. A total of 1,308 GBYR lengths were available from
743 the study and were assumed to all be from retained fish. Ally et al. (1991) conducted an
744 onboard observer program of the CPFV fleet from 1985-1987 in southern California. Because
745 MRFSS data were available for this time period as well and represents multiple recreational
746 modes, the Ally et al. (1991) length data were not used in the assessment.

747 *MRFSS Recreational Length Data, 1980-1989 and 1993-2003*

748 Unsexed length data of retained fish were collected by MRFSS dockside samplers and down-
749 loaded from the RecFIN website. We identified a subset of lengths that were converted from
750 weight measurements, and these were excluded from the final data set (Table 2). The length
751 measurements from Collins and Crooke (n.d.) from 1975-1978 are assumed to all be from
752 retained fish. As of 2003, the CDFW Onboard Observer program has taken length mea-
753 surements for discarded fish. The retained catch is measured during the dockside (angler
754 intercept) surveys.

755 The number of CPFV trips used as initial sample sizes for the MRFSS was based on the
756 number of CPFV trips was determined from the trip-level MRFS CPFV database and the
757 number of private boat trips was determined based on unique combinations of the vari-
758 ables ASSNID ,ID_CODE, MODE_FX, AREA_X, DIST, INTSITE, HRSF, CNTRBTRS,
759 SUB_REG, WAVE, YEAR, and CNTY in the Type 3 (sampler-examined catch) data.

760 During the recent restructuring of the CRFS data on RecFIN, a “trip” identifier was not
761 carried over for all modes, and trip-level sample sizes could not be extracted from the bio-

logical detail table on RecFIN. A proxy for initial sample sizes for 2004-2018 were developed using the 2015 data for which I had access to raw data files by mode from CDFW. In more recent years, sampling of the shore-based modes has declined and were not sampled at all in 2018. Samples sizes were calculated by mode as the number of port-days (or site-days for shore-based modes) during bi-weekly intervals (e.g., Jan 1-15, Jan 16-31, etc). The number of port-days sampled in the bi-weekly intervals was used as the initial sample size for number of trips to calculate initial input sample sizes using Ian Stewart's method (described above). All length data were re-weighted in the assessment model.

2.1.6 Fishery-Dependent Indices of Abundance

fishery-dependent-indices-of-abundance

A summary of all indices in the assessment can be found in Table 5. Figure 12 shows each index scaled to the mean value of that index to show them all on the same scale, i.e., the mean of each index in the plot is 1.

MRFSS Dockside CPFV Index

From 1980 to 2003 the MRFSS program conducted dockside intercept surveys of recreational fishing fleet. The program was temporarily suspended from 1990-1992 due to lack of funding. For purposes of this assessment, the MRFSS time series was truncated at 1998 due to sampling overlap with the onboard observer program (i.e., the same observer samples the catch while onboard the vessel and also conducts the dockside intercept survey for the same vessel). Each entry in the RecFIN Type 3 database corresponds to a single fish examined by a sampler at a particular survey site. Since only a subset of the catch may be sampled, each record also identifies the total number of that species possessed by the group of anglers being interviewed. The number of anglers and the hours fished are also recorded. The data, as they exist in RecFIN, do not indicate which records belong to the same boat trip. A description of the algorithms and process used to aggregate the RecFIN records to the trip level is outlined Supplemental Materials ("Identifying Trips in RecFIN").

Initial trip filters included eliminating trips targeting species caught near the surface waters for all or part of the trip, including trips with catch of bluefin tuna, yellowfin tuna, skipjack, and albacore. Trips occurring in bays were also excluded.

The following filtering steps were applied to gopher rockfish, as well as the sum of the two species to represent GBYR. No filtering or indices were developed for black-and-yellow rockfish alone due to the sparseness in the data. In the raw data, unfiltered data, black-and-yellow rockfish only occurred in 48 trips that did not also observe gopher rockfish. There were an additional 65 trips that encountered both species. There was little difference between indices developed for gopher-only and the GBYR complex for both north and south of Point Conception (Figure 13). The descriptions of the filtering and data below represent those for the GBYR complex.

798 The species composition of catch in California varies greatly with latitude.
799 Therefore, Stephens-MacCall filtering was applied independently for north and south of Point
800 Conception. Separate indices were also developed to represent two recreational fleets in the
801 model. Since recreational fishing trips target a wide variety of species, standardization of
802 the catch rates requires selecting trips that are likely to have fished in habitats containing
803 GBYR. The Stephens-MacCall (2004) filtering approach was used to identify trips with a
804 high probability of catching GBYR, based on the species composition of the catch in a given
805 trip. Prior to applying the Stephens-MacCall filter, we identified potentially informative
806 predictor species, i.e., species with sufficient sample sizes and temporal coverage (at least 30
807 positive trips total) to inform the binomial model. Coefficients from the Stephens-MacCall
808 analysis (a binomial GLM) are positive for species which co-occur with GBYR, and negative
809 for species that are not caught with GBYR. Each of these filtering steps and the resulting
810 number of trips remaining in the sampling frame are provided in Table 18.

811 *MRFSS Filtering and Index Standardization for North of Point Conception.* Prior to the
812 Stephens-MacCall filter, a total of 2,788 trips were retained for the analysis. As expected,
813 positive indicators of GBYR trips include several species of nearshore rockfish, treefish, kelp
814 rockfish, and blue rockfish, and the strongest counter-indicator was striped bass (Figure
815 14). While the filter is useful in identifying co-occurring or non-occurring species assuming
816 all effort was exerted in pursuit of a single target, the targeting of more than one target
817 species can result in co-occurrence of species in the catch that do not truly co-occur in
818 terms of habitat associations informative for an index of abundance. Stephens and MacCall
819 (Stephens and MacCall 2004) recommended including all trips above a threshold where the
820 false negatives and false positives are equally balanced. However, this does not have any
821 biological relevance and for this data set, we assume that if a GBYR was landed, the anglers
822 had to have fished in appropriate habitat, especially given how territorial GBYR and both
823 species are strongly associated with rocky habitat.

824 Two levels of possible filtering were applied using the Stephens-MacCall filter (Table 18).
825 The Stephens-MacCall filtering method identified the probability of occurrence (in this case
826 0.4) at which the rate of “false positives” equals “false negatives.” The trips selected using
827 this criteria were compared to an alternative method including all the “false positive” trips,
828 regardless of the probability of encountering GBYR (Table 21). This assumes that if GBYR
829 were caught, the anglers must have fished in appropriate habitat during the trip. The catch
830 included in this index is “sampler-examined” and the samplers are well trained in species
831 identification. The last filter applied was to exclude years after 1999 due to a number of
832 regulation changes, and years in which there were less than 20 observed trips. The final
833 index is represented by 544 trips, 220 of which encountered GBYR.

834 Due to the large number of zeros in the data, we modeled catch per angler hour (CPUE;
835 number of fish per angler hour) using maximum likelihood and Bayesian negative binomial
836 regression. Models incorporating temporal (year, 2-month waves) and geographic (region
837 and area_x) factors were evaluated. Counties were grouped into three regions, north of
838 Sonoma county, Sonoma county through Santa Cruz county, and San Luis Obispo county.
839 Based on AIC values from maximum likelihood fits (Table 19), a main effects model including

840 all factors (year, region, area_x, and 2-month waves) was fit in the “rstanarm” R package
841 (version 2.18.2). Diagnostic checks of the Bayesian model fit (Neff, Rhat, and Monte Carlo
842 standard error values) were all reasonable. Predicted means by stratum (Year) were strongly
843 correlated with observed means, suggesting a reasonable fit to the data (Figure 16). The
844 NB model generated data sets with roughly 50-70% zeros, compared to the observed 60%
845 (Figure 17).

846 The index represents the years 1984-1989, 1995, 1996 and 1999. There is not a lot of contrast
847 in the index, except for a small increase in 1986. The final index values and associated log
848 standard error included in the assessment can be found in Table 6.

849 *MRFSS Filtering and Index Standardization for South of Point Conception.* Note, the
850 MRFSS index for south of Point Conception was not used in the post-STAR base model.
851 Prior to the Stephens-MacCall filter, a total of 7,334 trips were available for the analy-
852 sis. As expected, positive indicators of GBYR trips included several nearshore species, e.g.,
853 kelp rockfish, treefish, and black croaker, while the strongest counter-indicator was opaleye
854 (Figure 18). While the filter is useful in identifying co-occurring or non-occurring species
855 assuming all effort was exerted in pursuit of a single target, the targeting of more than one
856 target species can result in co-occurrence of species in the catch that do not truly co-occur
857 in terms of habitat associations informative for an index of abundance. For consistency with
858 the methods used north of Point Conception (Table 18) the index includes the trips identified
859 as “false positives” from the Stephens-MacCall filtering that had a lower threshold level of
860 0.22 (Table 22). The last filter applied was to exclude years after 1999 due to a number
861 of regulation changes, and years in which there were less than 20 observed trips. The final
862 index is represented by 475 trips, 342 of which encountered GBYR.

863 Catch per angler hour (CPUE; number of fish per angler hour) was modeled using the delta-
864 GLM approach (Lo et al. 1992, Stefánsson 1996). A negative binomial model was explored,
865 but the proportion of zeroes was not well estimated in the negative binomial models. This
866 is likely due to the facts that MRFSS sampling effort was higher south of Point Conception,
867 and GBYR are also rare south of Point Conception, both leading to a higher proportion of
868 zeroes in the trip data than for north of Point Conception.

869 Model selection using Akaike Information Criterion (AIC) supported inclusion of year, region,
870 area_x, and 2-month waves. Counties were grouped into three regions, Santa Barbara to
871 Ventura counties, Los Angeles and Orange counties, and San Diego county for both the
872 positive observation model and the binomial model. Area_x is a measure of distance from
873 shore, a categorical variable indicating whether most of the fishing occurred inside or outside
874 three nautical miles from shore.

875 The resulting index for south of Point Conception represents different years than the index for
876 north of Point Conception (Table 6). The index starts in 1980 with continuous data through
877 1986, and three additional years in 1996, 1998 and 1999. The index increases through 1983
878 and a marked decrease to 1986. The index for the three years in the 1990s does not exhibit
879 any significant trend.

880 **CPFV Onboard Observer Surveys**

881 Onboard observer survey data were available from three sources for this assessment, 1)
882 a CDFW survey in central California from 1987-1998 (referred to as the Deb Wilson-
883 Vandenberg onboard observer survey, (Reilly et al. 1998)), 2) the CDFW CPFV onboard
884 observer survey from 1999-2018, and 3) a Cal Poly survey from 2003-2018. During an on-
885 board observer trip the sampler rides along on the CPFV and records location-specific catch
886 and discard information to the species level for a subset of anglers onboard the vessel. The
887 subset of observed anglers is usually a maximum of 15 people the observed anglers change
888 during each fishing stop. The catch cannot be linked to an individual, but rather to a specific
889 fishing location. The sampler also records the starting and ending time, number of anglers
890 observed, starting and ending depth, and measures discarded fish.
891 The fine-scale catch and effort data allow us to better filter the data for indices to fishing
892 stops within suitable habitat for the target species.

893 The state of California implemented a statewide sampling program in 1999 (Monk et al.
894 2014). California Polytechnic State University (Cal Poly) has conducted an independent
895 onboard sampling program as of 2003 for boats in Port San Luis and Morro Bay, and follows
896 the protocols established in Reilly et al. (1998). Cal Poly has modified protocols reflect
897 sampling changes that CDFW has also adopted, e.g., observing fish as they are encountered
898 instead of at the level of a fisher's bag. Therefore, the Cal Poly data area incorporated in
899 the same index as the CDFW data from 1999-2018. The only difference is that Cal Poly
900 measures the length of both retained and discarded fish.

901 We generated separate relative indices of abundance in for the 1987-1999 and 2000-2018
902 data sets due to the number of regulation changes occurring throughout the time period (see
903 Appendix B). Separate indices were also developed for north and south of Point Conception.

904 *Deb Wilson-Vandenberg Onboard Observer Index Filtering and Standardization.* A large
905 effort was made by the SWFSC to recover data from the original data sheets for this
906 survey and developed into a relational database (Monk et al. 2016). The specific fishing
907 locations at each fishing stop were recorded at a finer scale than the catch data for this survey.
908 We aggregated the relevant location information (time and number of observed anglers) to
909 match the available catch information. Between April 1987 and July 1992 the number of
910 observed anglers was not recorded for each fishing stop, but the number of anglers aboard the
911 vessel is available. We imputed the number of observed anglers using the number of anglers
912 aboard the vessel and the number of observed anglers at each fishing stop from the August
913 1992-December 1998 data (see Supplemental materials for details). In 1987, trips were only
914 observed in Monterey, CA and were therefore excluded from the analysis. The years 1990
915 and 1991 were also removed for low sample sizes. Final data filters included removing reefs
916 that never encountered GBYR, drifts that had fishing times outside 95% of the data, and
917 fishing stops with depths <9 m and >69m. The final data set contained 2,411 fishing stops,
918 with 1,096 of those encountering GBYR (Figure 19).

919 The index was fit using a delta-GLM model, with a lognormal model (AIC: 1,088) selected
920 over a gamma model (AIC: 1,143) for the positive encounters. Covariates considered in

the full model included year, depth, and month (Table 8). The model selected by AIC for both the lognormal and binomial components of the delta-GLM included year, depth and reef. Depth was included in 10 m depth bins and eight reefs were select in the final model (Figure coming). The final index did not indicate an increasing trend that was seen in the 2005 gopher rockfish assessment using the same data set (Figure 20). A number of reasons include that finer-scale location data was keypunched in 2012 for this survey, the index in this assessment includes black-and-yellow rockfish, and different filters were applied to the data. However, the the same peaks and decreases in the two indices are present.

CDFW and Cal Poly Onboard Observer Index Filtering and Standardization As described above the CDFW and Cal Poly onboard observer programs are identical in that the same protocols are followed. The only difference is that Cal Poly measures both retained and discarded fish from the observed anglers and CDFW measures only discarded fish from the observed anglers. CDFW measures retained fish as part of the angler interview at the bag and trip level. Cal Poly has also begun collecting otoliths during the onboard observer trips, which are used as conditional age-at-length data the recreational fishery north of Point Conception in this assessment.

A number of filters are applied to these data. All of the Cal Poly data have been through a QA/QC process once key-punched, whereas a number of errors remain in the data from CDFW. Data sheets from CDFW are no longer available prior to 2012 and staff constraints have also prevented a quality control review of the data.

Each drift was assigned to a reef (hard bottom). Hard bottom was extracted from the California Seafloor Mapping Project, with bathymetric data from state waters available at a 2 m resolution. Reefs were developed based on a number of factors described in the supplemental material (“Reef Delineation”).

Initial filters were applied to the entire data set, north and south of Point Conception combined. After an initial clean-up of the data, 67,850 drifts remained, with GBYR present in 9,317 (Table 9). This was reduced to 25,427 drifts with GBYR present in 7,250 drifts after filtering the data to remove potential outliers in the time fished and observed anglers, limiting the data to reefs that observed GBYR and were sampled in at least 2/3 of all years, and to drifts with starting locations within 1,000 m of a reef.

Recreational fishing trips north and south of Point Conception can be fundamentally different due to differences in habitat structure, target species, and weather.

Filtering and Index Standardization for north of Point Conception The number of drifts remaining before region specific filtering was 13,792, with 6,036 drifts encountering GBYR (Table 9).

Because GBYR are strongly associated with hard bottom habitat, the distance from a reef at the start of a drift was re-examined for drifts encountering GBYR. The maximum distance was 872 m, but the 97% quantile dropped to 42 m and was chosen as a reasonable cutoff value, and only resulted in a reduction of 182 drifts that encountered gopher rockfish. The

960 final data were filtered to ensure all selected reefs were sampled in at least 2/3 of all years,
961 leaving 12,965 drifts for the final index, 5,796 of which encountered GBYR (Figure 21).

962 The index of abundance was modeled with a delta-GLM modeling approach, with year,
963 month, 10 m depth bins from 10-59 m, and 12 reefs as possible covariates. A lognormal
964 model (AIC: 12,185) was selected over a gamma (AIC: 12,520) for the positive observations
965 using AIC. The full model was selected by AIC for the lognormal and binomial components
966 of the delta-GLM. The index indicates a relatively stable trend from 2001-2009 and a steady
967 decrease from 2010-2013. The relative index of abundance has increased since 2014.

968 *Filtering and Index Standardization for south of Point Conception* Note, the CPFV onboard
969 index for south of Point Conception was not used in the final post-STAR base model. The
970 bathymetric data is not available at as fine-scale resolution for the Southern California Bight
971 and more of the trips and drifts target mid-water species, including mid-water rockfish (Table
972 9). Therefore, instead of using distance to reef as a filter, we filtered the data to drifts that
973 encountered 20% or more groundfish. This resulted in the total number of drifts decreasing
974 from 11,635 to 5,495, but only decreased the number of drifts encountering GBYR from
975 1,277 to 1,171. A final check was made to ensure all reefs were sampled in at least 2/3 of all
976 years, leaving 5,440 drift for the final index, of which 1,132 encountered GBYR (Figure 22).

977 The index of abundance was modeled with a delta-GLM modeling approach, with year,
978 month, 10 m depth bins from 10-59 m, and four reefs as possible covariates. A lognormal
979 model (AIC: 162) was selected over a gamma (AIC: 277) for the positive observations using
980 AIC. A model with year, depth and reef was selected by AIC for both the lognormal and
981 binomial components of the delta-GLM. The index indicates a relatively stable trend from
982 2001-2004 and a steady increase from 2005-2017.

983 2.1.7 Fishery-Dependent Indices: Available Length and Age Data fishery-dependent-indices-available-length-and-age-data

984 Length data associated with the MRFSS dockside CPFV survey and the current onboard ob-
985 server surveys conducted by CDFW are incorporated into the biological data pulled from the
986 respective data sources, MRFSS and CRFS. The additional length data are not incorporated
987 as separate length composition data as they represent the same portion of the population
988 sampled by the CDFW onboard observer program.

989 Cal Poly collected otoliths from the onboard observer program starting in 2017 as part of a
990 special study to correlate fish length before and after the fish was filleted by the deckhands
991 onboard the CPFV vessels. All fish collected in 2017 only had associated post-fillet lengths
992 and were not used in the assessment since the study has not been finalized nor has the
993 method been endorsed by the SSC. A subset of fish from the 2018 collection included both
994 pre- and post-fillet length and were used in the assessment as conditional age-at-length data
995 associated with the recreational fleet north of Point Conception.

996 Length composition from Deb Wilson-Vandenberg's onboard observer survey are included
997 in the assessment. This program measured both retained and discarded fish, and represent
998 the portion of the population sampled with the spatial extent of the index. This onboard
999 observer program continued during the period from 1990-1992 when MRFSS was on hiatus.

1000 **2.1.8 Fishery-Independent Data Sources**

fishery-independent-data-sources

1001 Neither of the two fishery-independent surveys described below have previously been used
1002 in stock assessments as indices of abundance.

1003 **California Collaborative Fisheries Research Project**

1004 The California Collaborative Fisheries Research Project, [CCFRP](#), is a fishery-independent
1005 hook-and-line survey designed to monitor nearshore fish populations at a series of sampling
1006 locations both inside and adjacent to MPAs along the central California coast (Wendt and
1007 Starr [2009](#), Starr et al. [2015](#)). The CCFRP survey began in 2007 and was originally designed
1008 as a statewide program in collaboration with NMFS scientists and fishermen. From 2007-
1009 2016 the CCFRP project was focused on the central California coast, and has monitored four
1010 MPAs consistently since then ([Figure 23](#)). In 2017, the program was expanded coastwide
1011 within California. The index of abundance was developed from the four MPAs sampled
1012 consistently (Año Nuevo and Point Lobos by Moss Landing Marine Labs; Point Buchon and
1013 Piedras Blancas by Cal Poly).

1014 The survey design for CCFRP consists a number 500 x 500 m cells both within and outside
1015 each MPA. On any given survey day site cells are randomly selected within a stratum (MPA
1016 and/or reference cells). CPFVs are chartered for the survey and the fishing captain is allowed
1017 to search within the cell for a fishing location. During a sampling event, each cell is fished for
1018 a total of 30-45 minutes by volunteer anglers. Each fish encountered is recorded, measured,
1019 and can be linked back to a particular angler, and released (or descended to depth). Starting
1020 in 2017, a subset of fish have been retained to collect otoliths and fin clips that provide needed
1021 biological information for nearshore species. For the index of abundance, CPUE was modeled
1022 at the level of the drift, similar to the fishery-dependent onboard observer survey described
1023 above.

1024 The CCFRP data are quality controlled at the time they are key punched and little filtering
1025 was needed for the index. Cells not consistently sampled over time were excluded as well as
1026 cells that never encountered GBYR. CCFRP samples shallower depths to avoid barotrauma-
1027 induced mortality. The index was constrained to 5-39m in 5 m depth bins. The final index
1028 included 4,920 drifts, 3,848 of which encountered GBYR.

1029 We modeled catch per angler hour (CPUE; number of fish per angler hour) using maximum
1030 likelihood and Bayesian negative binomial regression. The proportion of zeroes in this data
1031 was relatively small (22%), and if overdispersion were not present, the regression would

1032 innately become Poisson. Models incorporating temporal (year, month) and geographic
1033 (MPA site and MPA vs Reference cells) factors were evaluated. Based on AIC values from
1034 maximum likelihood fits (Table 17), a main effects model including all factors (year, month,
1035 site and MPA/REF) was fit in the “rstanarm” R package (version 2.18.2). Diagnostic checks
1036 of the Bayesian model fit (Neff, Rhat, and Monte Carlo standard error values) were all
1037 reasonable. Predicted means by stratum (Year) were strongly correlated with observed
1038 means, suggesting a reasonable fit to the data (Figure 24). The NB model generated data
1039 sets with roughly 18-22% zeros, compared to the observed 22% (Figure 17).

1040 The CCFRP index of abundance closely matches the trend observed in the onboard observer
1041 index from 2009-2018 (Figure 12). The index decreases from 2009 to 2013, and then exhibits
1042 the same increase through 2018. When both indices are standardized to their means, the
1043 values for 2013 and 2018 are the same.

1044 *CCFRP Length Measurements and Available Ages*

1045 The CCFRP program measures every fish encountered to the nearest half centimeter. A
1046 total of 22,470 GBYR were measured by CCFRP from 2007-2018, of which only 212 were
1047 black-and-yellow rockfish. The length distributions for each of the four MPAs used in the
1048 index for this assessment show slight difference in their peaks (Figure 26). Año Nuevo is the
1049 most northern site and Point Buchon the most southern.

1050 Conditional age-at-length data were also incorporated into the assessment from the CCFRP
1051 program, including two master’s theses that are products of the CCFRP. Erin Loury (Loury
1052 2011) collected gopher rockfish otoliths as part of her thesis work from 2007-2009 that in-
1053 cluded specimens from both inside and outside the MPAs. Natasha Meyers-Cherry (Meyers-
1054 Cherry 2014) conducted another thesis focused on the life history of gopher rockfish and
1055 collected otoliths from 2011-2012, also both inside and outside the MPAs. Both MLML and
1056 Cal Poly began routinely collecting otoliths from a select number of fish in 2017 as part of
1057 the CCFRP program. Also included in the conditional age-at-length data for this fleet are
1058 otoliths collected in 2018 by the University of California Davis Bodega Marine Lab CCFRP
1059 program.

1060 **Partnership for Interdisciplinary Studies of Coastal Oceans**

1061 The Partnership for Interdisciplinary Studies of Coastal Oceans, [PISCO-UCSC](#), conducts
1062 a number of surveys to monitor the kelp forests, one of which is a kelp forest fish survey.
1063 PISCO has monitored fish population in the 0-20 m depth range as part of the Marine Life
1064 Protection Act (MLPA) since 1998. Paired sites inside and outside MPAs are surveyed to
1065 monitor the long-term dynamics of the kelp forest ecosystem and provide insight into the
1066 effect of MPAs on kelp forest species. PISCO conducts the fish surveys from late July through
1067 September. At each site, benthic, midwater, and canopy scuba transects are conducted at
1068 5, 10, 15, and 20 m depth. All divers are trained in species identification. Along each 30
1069 m transect, divers enumerate all identifiable non-cryptic fish, and measure total length to
1070 the nearest centimeter. PISCO surveys are conducted by the University of California Santa

1071 Cruz (UCSC) in central California and through the University of California Santa Barbara
1072 in southern California. All PISCO data were provided by Dan Malone (UCSC).

1073 The majority of filtering for the PISCO data set was to determine which sites to retain for
1074 the final index. After initial filtering the data for GBYR in southern California were too
1075 sparse to be considered for the index of abundance. Gopher and black-and-yellow rockfish
1076 were also rarely observed in the midwater and canopy transects, and therefore the index is
1077 based only on the benthic transects. Only sites sampled consistently throughout the time
1078 period 2001-2018 were kept for the index. Multiple transects can be conducted along the
1079 same line within a sampling event. All transects within a site were combined and effort was
1080 modeled as the number of transects represented in the number of fish observed. The final
1081 index included 3,231 transects, of which 1,729 observed GBYR (Figure 27).

1082 Three indices are described below. The pre-STAR base model includes a single index of
1083 abundance for the PISCO survey. During the STAR panel the decision was made to include
1084 two separate indices of abundance and selectivities for the PISCO data. The PISCO data
1085 include information on age-0 recruitment and also older fish. The PISCO age-0 recruitment
1086 index includes fish that are 6 cm or smaller, and the PISCO index for larger fish includes
1087 fish 15 cm and larger. There is uncertainty in the age of fish in the 7-14 cm range due to
1088 the timing of sampling, growth, and the timing of ages, i.e., all fish turn one on Jan 1 in the
1089 SS assessment model. FIsh in teh 7-14 cm are also not well sampled by the survey.

1090 For all three iterations of the index we modeled number of fish observed per transect(s)
1091 using maximum likelihood and Bayesian regression. The index containing all data and the
1092 index for larger fish (15+ cm) only were modeled as negative binomial, whereas the data
1093 for the age-0 index were sparse and modeled as binomial. Models incorporating temporal
1094 (year, month) and geographic (site and zone) factors were evaluated. The zone is a factor
1095 indicating the depth stratification at a site, i.e., 5 m, 10 m, 15 m, or 20 m targeted bottom
1096 depth.

1097 *Index based on all of the PISCO data (used in the pre-STAR base model).*

1098 Based on AIC values from maximum likelihood fits (Table 13), a main effects model including
1099 all factors (year, month, site and zone) was fit in the “rstanarm” R package (version 2.18.2).
1100 Diagnostic checks of the Bayesian model fit (Neff, Rhat, and Monte Carlo standard error
1101 values) were all reasonable. Predicted means by stratum (Year) were strongly correlated
1102 with observed means, suggesting a reasonable fit to the data (Figure 28). The NB model
1103 generated data sets with roughly 16-25% zeros, compared to the observed 23% (Figure 29).

1104 The final index decreases from 2001 to the late 2000s, with lower estimates of relative abun-
1105 dance from 2005-2010. From 2010 to 2015, the index increases and peaks in 2015, before
1106 the decreasing trends from 2016-2018. The trend observed in this index is counter to that
1107 observed in the onboard observer and CCFRP indices for north of Point Conception (Fig-
1108 ure 12). The PISCO survey is sampling different habitat types than the other two surveys,
1109 and covers much shallower depths. It’s possible that the PISCO index captures recruitment
1110 pulses, but because this index includes both young-of-the-year and adult fish, the trend may
1111 be captured in the model.

PISCO index based on fish 15 cm and larger (used in the post-STAR base model).
The same filtered dataset was used for the index for fish 15 cm and larger as for the PISCO index that included all fish. Based on AIC values from maximum likelihood fits (Table 14), a main effects model including all factors (year, month, site and zone) was fit in the “rstanarm” R package (version 2.18.2). Diagnostic checks of the Bayesian model fit (Neff, Rhat, and Monte Carlo standard error values) were all reasonable. Predicted means by stratum (Year) were strongly correlated with observed means, suggesting a reasonable fit to the data (Figure 30). The NB model generated data sets with roughly 20-30% zeros, compared to the observed 25% (Figure 31).

PISCO recruitment index based on fish 6 cm and smaller (used in the post-STAR base model).
The same filtered dataset was used for the index for fish 15 cm and larger as for the PISCO index that included all fish. There was no consistent pattern in the presence of age-0 fish to exclude any sites or zones. All years were included in the final index, even if sample sizes were small. Age-0 fish were present in 14% of all transects. A negative binomial model was not well fit to the data so a binomial (presence/absence) model was selected for the recruitment index. Based on AIC values for maximum likelihood fits (Table 15), a main effects model including year, month, and zone was fit in the “rstanarm” R package (version 2.18.2). The resulting index has large standard errors for years with sparse data, including 2004-2008 and 2012-2013. A recruitment signal is present in the index in a number of years, including 2001-2003, 2010, and 2014-2017.

PISCO Length Measurements

Every GBYR observed by PISCO divers except one, had an associated length measurement ($N = 11,965$). Divers measure fish to the nearest centimeter, and are trained to measure fish underwater and be aware of possible biases, e.g., ambient light, body color, visibility, and body shape. Both juvenile and adult GBYR were observed in the PISCO kelp forest fish survey data (Figure 32). Of note is the similarity in length distributions both between the species and for the two species combined across sites. Fish in the 10-17 cm size range (approximately) are not observed in this survey. There is significant post-settlement mortality for both species, which is thought to be due to density-dependent predation (Johnson 2006, 2007). Secondly, both species are cryptic and observed more often at night than during the day (Mark Carr, PISCO-UCSC, personal communication).

2.1.9 Biological Parameters and Data

`biological-parameters-and-data`

Neither gopher nor black-and-yellow rockfish have forked tails, therefore total length and fork length are equal. All of the data provided for this assessment were either in fork length or total length.

(Table 4)

Length and Age Compositions

1149 Length compositions were provided from the following sources:

- 1150 • CALCOM (*commercial retained dead fish*, 1987, 1992-2018)
- 1151 • WCGOP (*commercial discarded fish*, 2004-2018)
- 1152 • Deb Wilson-Vandenberg's onboard observer survey (*recreational charter retained and*
1153 *discarded catch*, 1987-1998)
- 1154 • California recreational sources combined (*recreational charter retained catch*)
 - 1155 – Miller and Gotshall dockside survey (1959-1966)
 - 1156 – Ally et al. onboard observer survey (1985-1987)
 - 1157 – Collins and Crooke onboard observer survey (1975-1978)
 - 1158 – MRFSS dockside survey (1980-2003)
 - 1159 – CRFS onboard and dockside survey (2004-2018)
- 1160 • PISCO dive survey (*research*, 2001-2018)
- 1161 • CCFRP hook-and-line survey (*research*, 2007-2018)

1162 The length composition of all fisheries aggregated across time by fleet is in Figure 33 and
1163 Table 4. Descriptions and details of the length composition data are in the above section for
1164 each fleet or survey.

1165 Age Structures

1166 A total of 2,421 otoliths were incorporated in this assessment and a summary by source can
1167 be found in Table 23. The final base model excludes the commercial age data that were
1168 sparse and not representative of the fishery. Gopher rockfish comprised 79% of the samples
1169 (922 females, 879 males, 121 unknown sex), and all but a few black-and-yellow rockfish (247
1170 females, 232 males, 20 unknown sex) came from a directed study by Jody Zaitlin (1986),
1171 collected from 1983-1986 (Figure 34).

1172 Of the available ages, 94% were collected during fishery-independent surveys.

1173 The remaining 6% were recreational dockside surveys and collected by Cal Poly during their
1174 CPFV onboard observer survey (36 otoliths) in 2018.

1175 All otoliths were read by Don Pearson (NMFS SWFSC, now retired) and estimated ages
1176 ranged from 1-28. The aged black-and-yellow rockfish ranged in length from 7-32 cm with a
1177 mean of 24 cm and gopher rockfish ranged in length from 11-36 cm, with a mean of 26. In
1178 terms of ages, the black-and-yellow rockfish ranged from 2-19 and gophers from 2-28. Fits
1179 to the von Bertalanffy growth curve (Bertalanffy 1938), $L_i = L_\infty e^{(-k[t-t_0])}$, where L_i is the
1180 length (cm) at age i , t is age in years, k is rate of increase in growth, t_0 is the intercept, and
1181 L_∞ is the asymptotic length, were explore by species and sex.

1182 No significant differences were found in growth between gopher and black-and-yellow rock-
1183 fishes (Figure 35) or between males and females (Figure 36), species combined.

1184 Aging Precision and Bias

1185 Uncertainty in ageing error was estimated using a collection of 376 gopher and black-and-
1186 yellow rockfish otoliths with two age reads (Figure 38). Age-composition data used in the
1187 model were from a number of sources described above. All otoliths were read by Don Pearson
1188 (NMFS SWFSC, no retired) who also conducted all blind double reads.

1189 Ageing error was estimated using publicly available software (Thorson et al. 2012). The
1190 software setting for bias was set to unbiased since the same reader conducted the first and
1191 second readings. The best fit model chose by AIC for the standard deviation was a constant
1192 coefficient of variation for reader one ad mirrored for reader two (Figure 39).

1193 The resulting estimate indicated a standard deviation in age readings increasing from 0.74
1194 years at age 0 to a standard deviation of 2.07 years at age 28, the first year of the plus group
1195 in the assessment model.

1196 Weight-Length

1197 The weight-length relationship is based on the standard power function: $W = \alpha(L^\beta)$ where
1198 W is individual weight (kg), L is length (cm), and α and β are coefficients used as constants.

1199 The weight-length relationships was estimated from the three studies, Loury (2011), Meyers-
1200 Cherry (2014) (both gopher rockfish only from CCFRP) and Zaitlin (Zaitlin 1986) (black-
1201 and-yellow rockfish only). Only one weight-length relationship was estimated for the GBYR
1202 complex. The estimated parameters are $\alpha = 8.84e^{-006}$ and $\beta = 3.25584$. The estimated
1203 relationship is similar to that estimated by Lea et al. (1999) for gopher rockfish (Figure
1204 40). The weight-length relationship estimated here was used in the assessment model to
1205 best represent the GBYR complex.

1206 Sex Ratio, Maturity, and Fecundity

1207 The sex ratio for GBYR is assumed to be 50:50 as there is no evidence to suggest otherwise.

1208 Zaitlin (1986) found that females reached 50% maturity at 17.5 cm or 4 years of age in Central
1209 California and were 100% mature by age 6, with the same age of maturity found in southern
1210 California though individuals were smaller at age. Echeverria (1987) estimated maturity for
1211 17 rockfish species in central California. She found the size at first maturity and the size
1212 at 50% maturity for male and female gopher rockfish to be 17 cm total length, and 100%
1213 mature by 21 cm. Black-and-yellow rockfish males and females were first mature at 14 cm,
1214 50% of females were mature at 15 cm, 50% of males mature at 16 cm. Male black-and-yellow
1215 rockfish were 100% mature at 20 cm and females at 19 cm. In southern California waters,
1216 both males and females were found to reach first maturity at 13 cm total length (Larson
1217 1980). We did not have any samples from southern California to re-analyze the maturity
1218 ogive for that portion of the population. Both Zaitlin and Echeverria estimated the maturity
1219 ogives using ages from whole otoliths. A sample of 151 black-and-yellow rockfish otoliths

1220 surface read by Zaitlin were also read by Don Pearson, and Zaitlin's ages were consistently
1221 younger than Pearson's, by up to nine years. All of the available otoliths for this assessment
1222 were re-aged using a combination of surface reading and break-and-burn methodology.

1223 The maturity data from Zaitlin (1986) (422 black-and-yellow rockfish) were re-analyzed along
1224 with samples from Meyers-Cherry (2014) (115 gopher rockfish). Combining the two data sets
1225 provided an updated maturity ogive for the GBYR complex females (Figure 37). The first
1226 observed mature fish was 19 cm and the length at 50% was 21.66 cm, larger than suggested
1227 from the estimate used by Key et al. (2005) in the 2005 assessment. After re-analyzing the
1228 available data, the length at which 50% of female gopher rockfish were mature was estimated
1229 at 23.33 cm, and was 21.26 cm for female black-and-yellow rockfish. An important note is
1230 that the smaller fish from these studies were black-and-yellow rockfish and the larger fish
1231 were gopher rockfish. Although not used in this assessment, the estimate of 50% maturity
1232 for 23 GBYR from these studies was 21.88 cm. The age at 50% mature increased in this
1233 assessment to 21.66 cm, which is 3.96 cm larger than the value used in the 2005 assessment.

1234 Mature females in central California release larvae between January and July, peaking in
1235 February, March, and May (Larson 1980, Lea et al. 1999, Love et al. 2002). Both species of
1236 GBYR release one brood per season (Love et al. 2002). Black-and-yellow rockfish females
1237 can produce 25,000 - 450,000 eggs spawning from January to May. Gopher rockfish females
1238 ranging between 176 and 307 grams carry approximately 249 eggs per gram of body weight
1239 (MacGregor 1970). The fecundity estimates used in this assessment were provided by E.J.
1240 Dick (NMFS SWFSC) from a meta-analysis of fecundity in the genus *Sebastes* (Dick et al.
1241 2017).

1242 Natural Mortality

1243 Hamel (2015) developed a method for combining meta-analytic approaches to relating the
1244 natural mortality rate M to other life-history parameters such as longevity, size, growth
1245 rate and reproductive effort, to provide a prior on M . In that same issue of ICESJMS,
1246 Then et al. (2015), provided an updated data set of estimates of M and related life history
1247 parameters across a large number of fish species, from which to develop an M estimator
1248 for fish species in general. They concluded by recommending M estimates be based on
1249 maximum age alone, based on an updated Hoenig non-linear least squares (nls) estimator
1250 $M = 4.899 * A_{max}^{-0.916}$. The approach of basing M priors on maximum age alone was one that
1251 was already being used for west coast rockfish assessments. However, in fitting the alternative
1252 model forms relating $-0.916M$ to A_{max} , Then et al. (2015) did not consistently apply their
1253 transformation. In particular, in real space, one would expect substantial heteroscedasticity
1254 in both the observation and process error associated with the observed relationship of M to
1255 A_{max} . Therefore, it would be reasonable to fit all models under a log transformation. This
1256 was not done. Reevaluating the data used in Then et al. (2015) by fitting the one-parameter
1257 A_{max} model under a log-log transformation (such that the slope is forced to be -1 in the
1258 transformed space (as in Hamel (2015)), the point estimate for M is:

$$M = \frac{5.4}{A_{max}} \quad (1)$$

1259 The above is also the median of the prior. The prior is defined as a lognormal with mean
 1260 $\ln \frac{5.4}{A_{max}}$ and SE = 0.4384343 (Owen Hamel, personal communication, NMFS). Using a max-
 1261 imum age of 28 the point estimate and median of the prior is 0.193, which is used as a prior
 1262 for in the assessment model and as a fixed quantity in the post-STAR base model.

1263 2.1.10 Environmental or Ecosystem Data Included in the Assessment *environmental-or-ecosystem-data-included-in-the-assessment*

1264 In this assessment, neither environmental nor ecosystem considerations were explicitly in-
 1265 cluded in the analysis. This is primarily due to a lack of relevant data and results of analyses
 1266 (conducted elsewhere) that could contribute ecosystem-related quantitative information for
 1267 the assessment.

1268 2.2 Previous Assessments

previous-assessments

1269 2.2.1 History of Modeling Approaches Used for this Stock *history-of-modeling-approaches-used-for-this-stock*

1270 This is the first full assessment to include data for black-and-yellow rockfish. Black-and-
 1271 yellow rockfish was assessed coastwide as a data poor species using Depletion-Based Stock
 1272 Reduction Analysis (DB-SRA) (Dick and MacCall 2010). The DB-SRA model assigned a
 1273 40% probability that the then recent (2008-2009) catch exceeded the 2010 OFL.

1274 Gopher rockfish south of Point Conception was assessed as a data poor species in 2010 (Dick
 1275 and MacCall 2010). A Depletion-Corrected Average Catch (DCAC) model was used due to
 1276 time constraints. The mean yield from the DCAC distribution was 25.5 mt.

1277 Gopher rockfish north of Point Conception ($34^{\circ}27'$ N. latitude) was first assessed as a full
 1278 stock assessment in 2005 (Key et al. 2005) using SS2 (version 1.19). The assessment was
 1279 sensitive to the CPFV onboard observer index of abundance (referred to as Deb Wilson-
 1280 Vandenberg's onboard observer index in this assessment). The final decision table was based
 1281 around the emphasis given to the index. The stock was found to be at 97% depletion.

1282 2.2.2 2005 Assessment Recommendations

assessment-recommendations

1283 The 2005 STAR panel only had one recommendation specific to gopher rockfish. However,
 1284 they had a number of generic rockfish recommendations that can be found in the STAR
 1285 panel report available [here](#).

1286 **Recommendation 1: Additional length and age composition data should be**
1287 **collected for gopher rockfish. This would help to characterize spatial and**
1288 **possibly temporal variation in growth**

1289

1290 2019 STAT response: Additional age and length data have been collected from a num-
1291 ber of sources, the majority of which have been fishery-independent studies, including
1292 two master's theses focused on gopher rockfish. Only a handful of otoliths have been
1293 collected for gopher rockfish south of Point Conception. Additional length composition
1294 data are available since the last assessment.

1295 **2.3 Model Description**

model-description

1296 The model descriptions in the following sections reflect decisions and modelling choices the
1297 STAT team made prior to the STAR panel. Changes from the pre-STAR base model to the
1298 final post-STAR base model are documented in the “Responses to the Current STAR Panel
1299 Requests” section. During the STAR panel, the following structure change were made; 1) the
1300 commercial retained and commercial discard fleets were combined into one commercial fleet,
1301 2) the MRFSS recreational dockside and the CRFS recreational onboard indices south Point
1302 Conception were removed, 3) the PISCO index was split into two indices, one representing
1303 fish 15 cm and larger and an age-0 index representing fish 6 cm or less. All of the figures
1304 and tables reflect the post-STAR final base model. The section on the PISCO index of
1305 abundance has been updated to reflect the change in the indices.

1306 While investigating convergence issues in the cowcod assessment, Richard Methot (NMFS)
1307 identified an issue with the performance of the ‘sfabs’ function in ADMB. This led to poor
1308 convergence during the iterative search for F_{SPR} under certain conditions. Dr. Methot
1309 resolved the issue, and provided a new ‘safe’ version of SS (V3.30.13.09) to the cowcod and
1310 GBYR STATS on June 28, followed by an optimized executable on June 30. Apart from the
1311 iterative F_{SPR} search mentioned above, other model outputs and analyses were unaffected
1312 by the change. All of the base model results were run in this newest version of SS.

1313 **2.3.1 Transition to the Current Stock Assessment**

transition-to-the-current-stock-assessment

1314 The first formal stock assessment for gopher rockfish was conducted in 2005 (Key et al.
1315 2005). There are two major differences between the 2005 assessment this assessment, 1) this
1316 assessment models gopher and black-and-yellow rockfish as a complex, and 2) this assessment
1317 includes the area south of Point Conception.

1318 The 2005 model conducted in SS2 version 1.19 was first transitioned to SS3.24z as a bridge
1319 model, before moving forward to SS3.30. Below, we describe the most important changes
1320 made since the last full assessment in 2005 and explain rationale for each change. Some of

1321 these items are changes due to structure changes with Stock Synthesis, and some denote
1322 parameters chosen for options that were not available in SS2 (version 1.19).

1323 Changes in the bridge model from SS2 version 1.9 to SS3.24z and SS3.30.13.09 include:

1324 The way growth is modeled for age-0 fish has changed. More recent versions of Stock Syn-
1325 thesis model length-at-age for fish below the first reference age (A_{min}) as linearly increasing
1326 from the initial length bin to the length given by the $L_{at}A_{min}$ parameter. The mini-
1327 mum population length bin was reduced from 10 cm in the 2005 assessment to 4 cm in this
1328 assessment. The timing of settlement was set at July to reflect the month at which
1329 the young-of-the-year are expected to be at 4 cm (Figure 43). The length data leading to
1330 this decision were provided by Diana Baetscher (UCSC) and were collected via Standard
1331 Monitoring Unit for the Recruitment of Fishes (SMURFs) (Ammann 2004) from the UCSC-
1332 PISCO kelp forest fish survey as part of her dissertation work on rockfish genetics (Baetscher
1333 2019).

1334 This stock assessment retains a single fleet for the commercial fishery, and also includes
1335 a commercial discard fleet. Data on commercial discards were not available for and not
1336 included in the 2005 assessment. The decision to retain one commercial fleet was made by
1337 examining the length distributions across species, fishing gears, and space, i.e., north and
1338 south of Point Conception (Figure 44). There is very little difference between the length
1339 composition of gopher and black-and-yellow rockfish landed in the commercial fleet north of
1340 Point Conception, which contributed 97% of the commercial landings from 1978-2018. The
1341 length distributions suggest that gopher rockfish south of Point Conception landed dead
1342 south of Point Conception are slightly smaller on average than north of Point Conception.
1343 However, there is not enough data available to justify splitting the commercial fishery north
1344 and south of Point Conception. The length compositions of discarded fish are small in all
1345 of the subplots, suggesting size-based discarding. Because Stock Synthesis is not set up to
1346 handle depth-dependent discard mortality rates and we're modelling two species as a complex
1347 with differing depth-dependent discard mortality rates, the time series of commercial discards
1348 was incorporated as a fleet.

1349 This assessment incorporates the area south of Point Conception, which was previously
1350 excluded from the 2005 assessment. The length composition data suggested that while the
1351 lengths of gopher and black-and-yellow rockfish were similar, fish encountered south of Point
1352 Conception were smaller (Figure 45). The recreational catches from the man-made/jetty
1353 mode are negligible and did not influence the decision to split the fleet at Point Conception.
1354 From 2005-2018, the man-made/jetty mode averaged 0.5% of the total recreational catch and
1355 discards north of Point Conception and 0.03% south of Point Conception. The similarity of
1356 the length distributions between species and among modes within a region were similar and
1357 justified one recreational fleet.

1358 The 2005 model was a length-based model. This assessment uses conditional age-at-length
1359 from fish aged from a number of sources (Table 23).

1360 Differences in both the recreational and commercial catches used in this assessment are
1361 described in detail in Section 1.5.

1362 The bias adjustment for recruitment deviations did not exist in SS2 (version 1.19). We set
1363 1973-2015 as the range of years with full bias adjustment to span the time series that was
1364 modeled.

1365 The previous assessment modeled selectivity of the commercial fleet as logistic curve, and
1366 both parameters for the logistic selectivity were estimated. Selectivity for both the recre-
1367 ational fleet and onboard CPFV survey were modeled using the double logistic. The current
1368 assessment uses the six parameter double normal for all fleets for which selectivity is es-
1369 timated and not mirrored. The MRFSS dockside CPFV surveys and the CPFV onboard
1370 observer surveys are mirrored to the recreational fishing fleets, north and south of Point
1371 Conception, respectively.

1372 The 2005 assessment did not include any time blocks. This assessment includes two time
1373 blocks for the commercial fleet (1916-1998 and 1999-2018). A 10-inch minimum size limit
1374 was placed on the commercial fleet in 1999, which was reflected in the CALCOM length
1375 composition data. No additional time blocks were added for the recreational fleet. GBYR
1376 are a minor component of the nearshore rockfish complex and no significant changes were
1377 detected in the landings or length composition during the time when regulations changed
1378 (1999-2002).

1379 The 2005 assessment considered two candidate fishery-dependent indices of abundance, the
1380 Deb Wilson-Vandenberg onboard observer CPFV survey and a dockside intercept survey
1381 from MRFSS and RecFIN from 1983-2003. However, the dockside index was removed at the
1382 request of the STAR panel, citing “did not provide a reliable measure of relative abundance
1383 due to changes in regulations and fishery targeting during the 1990s-2000s.” The current
1384 assessment uses a version of the MRFSS database that has been more robustly aggregated
1385 to the trip level. Starting in 1999, the CDFW began angler interviews. Interviews are
1386 conducted for all the anglers on the boat, whereas the onboard data is only collected for a
1387 subset of anglers that changes with each fishing stop. Once the onboard observer program
1388 ramped up by the mid-2000s, almost all of the CPFV groundfish trips sampled as onboard
1389 observer trips were also sampled as angler interviews. Using both the onboard observer data
1390 and the dockside interviews for this time period would result in developing indices from the
1391 same fish. The fine-scale onboard observer data provides greater detail in terms of catch and
1392 location than the angler interviews. The onboard observer indices do not include the years
1393 1999 and 2000 due to the number of regulation changes occurring in those two years.

1394 The fishery-independent indices are all new for this assessment; the PISCO kelp forest fish
1395 survey and the CCFRP hook-and-line survey.

1396 Maturity was changed for this assessment based upon newly available data described in the
1397 biological specifications of this assessment.

1398 The 2005 assessment pre-STAR base model fixed steepness for gopher rockfish at 1.0, which
1399 was then changed to 0.65 (the Dorn prior at the time) during the STAR panel. In this
1400 assessment, steepness was set at 0.72, the mean of the prior developed from a meta-analysis of
1401 West Coast groundfish, with a standard deviation of 0.16 (see Accepted Practices Guidelines
1402 for Groundfish Stock Assessments in the supplemental material).

1403 The prior for female natural mortality was updated to the median of the prior from a meta-
1404 analysis conducted by Owen Hamel (see Accepted Practices Guidelines for Groundfish Stock
1405 Assessments in the supplemental material). Assuming a maximum age of 28 years, the
1406 median of the prior is 0.193, close to the fixed value used in the 2005 assessment of 0.2.

1407 Due to the fact that the 2005 model only included gopher rockfish and excluded the area
1408 south of Point Conception, a complete bridge model was not developed. Comparison of
1409 the 2005 input data, catch streams, and indices are provided throughout the document in
1410 appropriate sections.

1411 2.3.2 Summary of Data for Fleets and Areas

summary-of-data-for-fleets-and-areas

1412 There are 10 fleets in the post-STAR base model. They include:

1413 *Commercial*: There is one commercial fleet the includes GBYR landed (all gears combined)
1414 and dead discards.

1415 *Recreational*: The recreational fishery include two fleets, one for north of Point Conception
1416 and one for south of Point Conception (all modes combined).

1417 *Fishery-Dependent Surveys*: There are five fishery-dependent survey fleets, all north of Point
1418 Conception. THere is one for MRFRSS CPFV dockside survey, one for the CDFW/Cal Poly
1419 onboard observer survey, and one from the Deb Wilson-Vandenberg CPFV onboard observer
1420 survey.

1421 *Research*: There are two main sources of fishery-independent data available the CCFRP
1422 survey and the PISCO kelp forest fish survey. The PISCO survey was split into two indicies
1423 in the post-STAR base, one representing age-0 recruitment and one for fish 15+ cm. A third
1424 survey fleet is included as a “dummy” fleet to allow incorporation of additional conditional
1425 age-at-length composition data from the Zaitlin and Abrams theses, the Pearson groundfish
1426 cruise, and the special study conducted during the SWFSC’s juvenile rockfish and ecosystem
1427 cruise. This dummy fleet includes 1,067 ages of gopher and black-and-yellow rockfish. This
1428 dummy fleet does not have any length composition data or catches associated with it.

1429 **2.3.3 Other Specifications**

other-specifications

1430 Stock synthesis has a broad suite of structural options available. Where possible, the ‘default’
1431 or most commonly used approaches are applied to this stock assessment. The assessment
1432 is a one-sex model, as no significant differences in growth between males and females was
1433 detected in external analyses.

1434 The length composition data for some years and fleets was small, and may not be represen-
1435 tative of the total catch. Length composition data were removed from the model if fewer
1436 than 20 fish were measured in a given year and fleet. From 1985-1989, two surveys measured
1437 fish from the recreational party/charter fleet, the Ally et al. (Ally et al. 1991) onboard
1438 observer survey and the dockside intercept survey. The number of trips and fish sampled by
1439 the onboard observer survey was far greater than the MRFSS survey and were used in the
1440 model. Initial input sample sizes were also capped at 400 for each set of length composition
1441 data.

1442 The time-series of landings begins in 1916 for the commercial fleet and in 1928 for the
1443 recreational fleet. This captures the inception of the fishery, so the stock is assumed to be
1444 in equilibrium at the beginning of the modeled period.

1445 The internal population dynamics model tracks ages 0-28, where age 28 is the ‘plus-group.’
1446 There are relatively few observations in the age compositions that are greater than age 28.
1447 The population length bins and the length composition length bins are set at 1-cm bins from
1448 fish 4-40 cm.

1449 The extra standard deviation parameter was added to all indices except the MRFSS dockside
1450 index for north of Point Conception and the PISCO age-0 index since both had relatively
1451 large estimated variances associated with them. The extra parameter was explored, but
1452 estimated to be on the lower bound, and was removed for the post-STAR base model.
1453 All other indices, including the recreational onboard observer index, CCFRP, and PISCO
1454 (15+ cm fish), were estimated with relatively small variances (10-20%) from their respective
1455 indices. Extra variance was estimated for these indices in the post-STAR base model.

1456 The following likelihood components are included in this model: catch, indices, discards,
1457 length compositions, age compositions, recruitment, parameter priors, and parameter soft
1458 bounds. See the SS technical documentation for details (Methot et al. 2019).

1459 Electronic SS model files including the data, control, starter, and forecast files can be found
1460 on the [PFMC ftp site](#).

1461 **2.3.4 Modeling Software**

modeling-software

1462 The STAT team used Stock Synthesis 3 version 3.30.13.09 (published on 6/28/2019) by
1463 Dr. Richard Methot at the NWFSC. This most recent version was used, since it included

1464 improvements and corrections to older versions. The r4SS package (GitHub release number
1465 v1.35.1) was used to post-process output data from Stock Synthesis.

1466 2.3.5 Data Weighting

1466 `data-weighting`

1467 Length composition and conditional-age-at-length (CAAL) compositions sample sizes for the
1468 base model were tuned by the “Francis method,” based on equation TA1.8 in Francis (2011),
1469 and implemented in the r4ss package. This approach involves comparing the residuals in the
1470 model’s expected mean length with respect to the observed mean length and associated
1471 uncertainty derived from the composition vectors and their associated input sample sizes.
1472 The sample sizes are then tuned so that the observed and expected variability are consistent.
1473 After adjustment to the sample sizes, models were not re-tuned if the bootstrap uncertainty
1474 value around the tuning factor overlapped 1.0.

1475 As outlined in the Best Practices, a sensitivity run was conducted with length and
1476 conditional-age-at-length (CAAL) compositions were re-weighted using the Ianelli-
1477 McAllister harmonic mean method (McAllister and Ianelli 1997). Additionally, weighting
1478 using the Dirichlet-Multinomial likelihood, that includes and estimable parameter (theta)
1479 that scales the input sample size, was explored. However, the model did not converge when
1480 the Dirichlet-Multinomial likelihood was applied to a number of the fleets with composition
1481 data. Given this, and the current challenges with this method described in the Stock
1482 Synthesis manual (Methot et al. 2019), the Francis weightings were applied in the pre-STAR
1483 and post-STAR base models. The final post-STAR base model was re-weighted twice at
1484 which point the Francis weights stabilized.

1485 A series of sensitivities were conducted to determine the need to estimate extra variability
1486 parameters were estimated and added to the survey CPUE indices, and described below in
1487 the Estimated Parameters section.

1488 2.3.6 Priors

1488 `priors`

1489 The log-normal prior for female natural mortality were based on a meta-analysis completed
1490 by Hamel (2015), as described under “Natural Mortality.” Natural mortality was estimated
1491 using with a prior of, 0.193 (with log-space sigma of 0.438) for an assumed maximum age of
1492 28. Natural mortality was fixed at the value of the prior in the post-STAR base model.

1493 The prior for steepness (h) assumes a beta distribution with parameters based on an update
1494 for the Thorson-Dorn rockfish prior (Dorn, M. and Thorson, J., pers. comm.), which was
1495 endorsed by the Science and Statistical Committee in 2019. The prior is a beta distribution
1496 with $mu=0.72$ and $sigma=0.16$. Steepness is fixed in the post-STAR base model at the
1497 mean of the prior.

1498 **2.3.7 Estimated and Fixed Parameters**

estimated-and-fixed-parameters

1499 A full list of all estimated and fixed parameters is provided in Table 26. Time-invariant,
 1500 growth is estimated in this assessment, with all SS growth parameters being estimated. The
 1501 log of the unexploited recruitment level for the Beverton-Holt stock-recruit function is treated
 1502 as an estimated parameter. The early annual recruitment deviations begin in 1960, with the
 1503 main recruitment deviations estimated from 1972-2018. The survey catchability parameters
 1504 are calculated analytically (set as scaling factors) such that the estimate is median unbiased,
 1505 which is comparable to the way q is treated in most groundfish assessments.

1506 The post-STAR base model has a total of 61 estimated parameters in the following categories:

- 1507 • Equilibrium recruitment (R_0) and 41 recruitment deviations
- 1508 • Five growth parameters
- 1509 • Four index extra standard deviation parameter, and
- 1510 • Ten selectivity parameters

1511 The estimated parameters are described in greater detail below and a full list of all estimated
 1512 and parameters is provided in Table 26.

1513 *Growth.* Five growth parameters were estimated for the one-sex model: three von Bertalanffy
 1514 parameters and two parameters for CV as a function of length-at-age related to variability
 1515 in length-at-age for small and large fish.

1516 *Selectivity.* Double-normal, asymptotic selectivity was estimated for all fleets with estimated
 1517 selectvity parameters.

1518 Three parameters were estimated for the recreational and commercial fleets, the peak, the
 1519 ascending width, and the selectivity at the first bin. Only the ascending width parameter
 1520 was estimated for the PISCO fleet for fish 15+ cm.

1521 The Deb Wilson-Vandenberg onboard observer fleet and the CCFRP fleet were mirrored to
 1522 the recreational fleet north of Point Conception.

1523 *Other Estimated Parameters.* Main recruitment deviations estimated from 1978 to 2018.
 1524 The post-STAR base model also included estimated recruitment deviations for the forecast
 1525 years, although these have no impact on the model estimates for the current year.

1526 Many variations of the base case model were explored during this analysis. Sensitivities to
 1527 asymptotic vs. domed selectivity were explored for the appropriate fisheries, e.g. commercial
 1528 fisheries and surveys, as well as estimating selectivity and mirroring fleet selectivities. Time

1529 blocked selectivity without the time block from 1999-2019 for the recreational fisheries was
1530 investigated.

1531 Much time was also spent tuning the advanced recruitment bias adjustment options.
1532 Sensitivities were performed to each of the thirteen advanced options for recruitment, e.g.,
1533 early recruitment deviation start year, early recruitment deviation phase, years with bias
1534 adjustments, and maximum bias adjustment. The final base model sets the first year of
1535 recruitment deviations just prior to when the majority of fishery/survey length composition
1536 are available.

1537 Several models were also investigated where steepness and natural mortality were either
1538 estimated, fixed at their respective priors.

1539 *Other Fixed Parameters.* The stock-recruitment steepness is fixed at the SSC approved
1540 steepness prior for rockfish of 0.72 and natural mortality is fixed at 0.193, the mean of the
1541 prior.

1542 2.4 Model Selection and Evaluation

model-selection-and-evaluation

1543 2.4.1 Key Assumptions and Structural Choices

key-assumptions-and-structural-choices

1544 Key assumptions in the model are that it is appropriate to model gopher and black-and-
1545 yellow rockfish as a complex. The catch histories are inseparable at this time, especially for
1546 the early commercial landings. The biological information available also precluded complete
1547 analyses of difference in growth, i.e., the majority of black-and-yellow rockfish aged were
1548 small fish and small fish were lacking for gopher rockfish. Data from both species were used
1549 to provide a complete picture of the growth curve.

1550 The assessment is a one area model with fleets as areas for the recreational fishery. There
1551 were only a handful of aged gopher rockfish from south of Point Conception, and not enough
1552 other biological information available that would have justified a multi-area model.

1553 2.4.2 Alternate pre-STAR Models Considered

alternate-pre-star-models-considered

1554 A number of models were run with different catch histories for the recreational fleet south of
1555 Point Conception, given that the catch histories were modified from the original data. None
1556 of the alternatives explored altered the model at any significant level due to the fact that
1557 the recreational catches south of Point Conception are relatively small. Results from select
1558 sensitivity runs compared to the base model are in Table 27.

1559 Two sensitivities were also performed altering the commercial discard catch history. The
1560 discard catch was set to zero for all years prior to 2004, the year when WCGOP estimates

1561 were first available, and to a constant rate of 17% of the commercial landings, the maximum
1562 discard rate observed in the WCGOP data. Neither of these sensitivities resulted in any
1563 significant change to the model outputs.

1564 Sensitivity of the model to the spawning and settlement months were also explored. The
1565 base model originally set settlement month to January. Both gopher and black-and-yellow
1566 rockfish settle at a small size (~2 cm) and over a course of several months. After exploring the
1567 young-of-the-year length data made available by Diana Baetscher, the timing of settlement
1568 was moved to July for the base model, when the majority of GBYR are 4 cm, the size of the
1569 smallest length bin. The change of the timing of settlement had little effect on the model
1570 results.

1571 Runs of the base case model estimating steepness were also considered.

1572 A sensitivity of the model to using the commercial length composition data from PacFIN
1573 was also considered. The fits changed only slightly, (increasing depletion from 0.46 to 0.48)
1574 but given the concerns outlined in the discussion on commercial length composition the base
1575 model includes the commercial length compositions from CALCOM.

1576 Sensitivities were developed to look at alternate selectivity patterns for the the commercial
1577 discard fleet and the CCFRP survey. Neither of the length compositions for these fleets
1578 observed larger fish. A time block for the commercial discard fishery was not considered
1579 since no length composition of discarded fish were available prior to 2004.

1580 **2.4.3 Uncertainty and Sensitivity Analyses to the pre-STAR base** **uncertainty-and-sensitivity-analyses-to-the-pre-star-base**

1581 A number of sensitivity analyses were conducted prior to the STAR panel, including:

- 1582 1. Fixing natural mortality at the prior of 0.193
- 1583 2. Fixing the von Bertalanffy k at the external estimate of 0.247
- 1584 3. Using the PacFIN expanded length composition data
- 1585 4. Data weighting scenarios including unweighted, harmonic means (McAllister-Ianelli
1586 method), and Francis weights

1587 The following sensitivities are based on the pre-STAR base model and indicate areas that the
1588 STAT identified as either areas of uncertainty or model sensitivities outlined in the Accepted
1589 Practices and Guidelines document. A summary of parameters for all sensitivity runs is in
1590 Table 27.

1591 Fixing either natural mortality or the von Bertalanffy k parameter results in a stock with
1592 higher spawning output in 2018 as compared to the base model (Figure 41).

1593 Fixing either M or k demonstrates the negative correlation between the two parameters. The
1594 von Bertalanffy k parameter is estimated at 0.12 when natural mortality (estimated at 0.21)
1595 and growth are both estimated. When natural mortality is fixed at the prior of 0.193, k is
1596 estimated at 0.14, but the two other growth parameters, $L1$ and $L2$ do not change much at
1597 all. When k is fixed to the external estimate of 0.247, natural mortality is estimated at 0.16,
1598 and the other growth parameters both decrease. A number of additional sensitivities to the
1599 growth parameters will be presented at the STAR panel.

1600 Replacing the CALCOM commercial length composition data with the PacFIN length com-
1601 position results in the stock at an overall lower level of biomass than the base model. Deple-
1602 tion in the final year with the PacFIN length composition is 0.50, compared to 0.46 in the
1603 base model. A detailed discussion on the decision to use the CALCOM length composition
1604 in the base model can be found in the discussion commercial length and age data, Section
1605 (2.1.3).

1606 Data weighting is an area of uncertainty for stock assessment, and research is ongoing to
1607 determine the effects of data weighting and the most appropriate initial sample sizes for
1608 length and age composition data. The base model used the Stewart sample sizes for initial
1609 sample sizes for the fishery data and either the Stewart sample sizes or number of “trips” for
1610 the survey sample sizes. Weighting the data by the harmonic mean resulted in a model with
1611 a total likelihood between the base model, which uses the Francis method for weighting, and
1612 the model with default weights (Figure 42). The end year spawning output is almost identical
1613 for the models using harmonic means and Francis weights, both of which down-weighted the
1614 composition data.

1615 The Francis weights in the base model were stable, and did not tend to serially decrease
1616 (down-weight) any of the data sets, which has been seen in other assessments. The final
1617 base model re-weights the composition data only once. As discussed above in the data
1618 weighting section, the Dirichlet-Multinomial weighting was explored, but a model with a
1619 positive definite Hessian was not identified with the pre-STAR base model.

1620 2.5 Response to the Current STAR Panel Requests

response-to-the-current-star-panel-requests

1621 **Request No. 1:** Develop catch curves from age data as appropriate during
1622 different periods of fishing intensity according to the model.

1623

1624 **Rationale:** To obtain an independent estimate of total mortality to better gauge
1625 natural mortality given the model uncertainty.

1626 **STAT Response:** The STAT created two catch curves using the available age data for
1627 gopher and black-and-yellow rockfish, one for the time period pre-2000 (629 available

1628 ages) and the second from 2000-2018 (1,791 available ages). The pre-2000 plot used
1629 fish aged eight and older, while the 2000-2018 plot used fish aged 13 and older. The
1630 estimate of total mortality (Z) was not very different between the two time periods,
1631 0.37 for the earlier period and 0.36 for the later years. If restricted to the same ages
1632 (13 and older), the earlier period would have a steeper decline.

1633 **Request No. 2: Remove the indices from the Southern fleets 7 and 11 from the
1634 model**

1635
1636 **Rationale:** These cover a small portion of the population and would not be expected
1637 to have the same trends as the majority of the population, are in conflict with the
1638 northern trends, and there is no straightforward way to combine North and South
1639 indices

1640 **STAT Response:** The STAT removed the two fishery-dependent indices representing
1641 the portion of the stock south of Pt. Conception, the CDFW MRFSS-era dockside
1642 survey and the CDFW CRFS-era onboard observer survey index. There were minor
1643 changes to the model, with the total likelihood going from 515 to 511 and the estimate
1644 of natural mortality going from 0.212 to 0.219.

1645 **Request No. 3: Add discard to commercial catch data in terms of both catch
1646 and compositions (by weighting comps by the number of fish discarded or
1647 retained), and remove selectivity time block. Apply discard rate back in
1648 time.**

1649
1650 **Rationale:** Simpler to have a single fleet for all commercial catch and the model is
1651 likely to better reflect the actual dynamics.

1652 **STAT Response:** Response under Request #3a.

1653 **Request No. 3a: Remove commercial length comp data from 2000-2003 in
1654 addition to request.**

1655
1656 **Rationale:** Length limit imposed in 2000 but length discards not available until 2004.
1657 Therefore, comp data from these years are not representative of total removals.

1658 **STAT Response:** The STAT combined the catches from the commercial retained
1659 and commercial discard fleets, to create one commercial fleet representing both catch
1660 streams. The length composition data from the two fleets from 2004-2017 were com-
1661 bined by weighting the length compositions by the catches from each fleet. Compared
1662 to the pre-STAR base, the model run for request 3a, reduced the number of estimated
1663 parameters by 10, and resulted in a decrease in natural mortality to 0.195. The overall
1664 model output did not change from the base model or the changes made from Request
1665 #2.

1666 **Request No. 4: Split PISCO survey such that the 0-age fish (4 and 5 cm) are
1667 in one survey and the 15 cm+ fish are in the other. Fix age selectivity to**

1668 age-0 only for the first fleet and use a logistic selectivity for the second fleet.

1669

1670 **Rationale:** To separate out the recruitment index in the survey and to simplify the

1671 selectivity assumptions for this fleet.

1672 **STAT Response:** Response under Request #4a.

1673 **Request No. 4a: Include all years of the recruitment index developed above.**

1674

1675 **Rationale:** Years with low numbers of 4 and 5 cm fish indicate low recruitment and

1676 provide contrast to years with large numbers of those fish.

1677 **STAT Response:** The STAT developed an index of abundance using only fish that

1678 were 5 cm or less and re-developed the length composition data for the PISCO survey

1679 representing fish 15 cm and larger. The effect of splitting the PISCO index into two

1680 indices, one for young of the year and one representing older fish resulted in dampening

1681 of the age-0 recruits seen in the previous models.

1682 **Request No. 5: Remove the auto-correlation recruitment.**

1683

1684 **Rationale:** Given the sensitivity run presented, auto correlation didn't make much

1685 of a difference in model results, and there was not adequate evidence in the data for

1686 auto-correlation.

1687 **STAT Response:** Removing the auto-correlation in recruitment resulted in no sig-

1688 nificant change to the model output.

1689 **Request No. 6: 1) Start recruit deviation in 1978 as main recruit devs. and 2)**

1690 **Start these in 2001. Turn off all early recruit devs in both cases.**

1691

1692 **Rationale:** The composition data does not seem to be informing the estimates of the

1693 recruitment deviations but maybe driven by the artifacts in the catch data. The early

1694 recruit deviations are uninformed and all in one direction. Recruitment indices start

1695 in 2001.

1696 **STAT Response:** Starting the recruitment deviations in 2001 did not produce a

1697 reasonable recruitment signal. Starting the recruitment deviations in 1978 provided

1698 reasonable recruitment deviations and is a more appropriate starting year given the

1699 lack of sufficient length data prior to this time period.

1700 **Request No. 7: Start from model shown at request 6(1). Fix M at 0.193 and let**

1701 **the model estimate k. Change the ramp to estimated level with up ramp**

1702 **from 1978 to 1979. Provide all appropriate diagnostics.**

1703

1704 **Rationale:** : STAT and STAR agree this was an improvement over the original base

1705 model.

1706 **STAT Response:** Requests 7 and 8 were conducted for comparison and the plots
1707 comparing the two requests are below Request 8. Fixing natural mortality at the
1708 mean of the prior results in an increase in the growth parameter k from 0.145 to 0.147
1709 from Request #6 due to the decrease in the modeled natural mortality rate.

1710 **Request No. 8: Determine if 6cm or larger fish should be included in PISCO
1711 recruitment index. If so, update the PISCO index and include the updated
1712 index in the model from request #7 (above).**

1714 **Rationale:** Better to use all appropriate data for the recruitment index.

1715 **STAT Response:** After an email discussion with Mark Carr, Dan Malone (UCSC
1716 PISCO) and Darren Johnson (CSU Long Beach) it was decided that fish of length 6 cm
1717 at the end of the year of birth would still all be young of the year fish during the months
1718 in which the PISCO survey is conducted. Additional research is needed to verify the
1719 appropriate lengths to include, perhaps by month. The PISCO age-0 index developed
1720 for this request resulted in a decrease the recruitment index in the early 2000s, and an
1721 increase in the recruitment index in 2010 and from 2014-2018 relative to include only
1722 4 and 5 cm individuals. The resulting models in the plot that used the revised PISCO
1723 age-0 index of abundance are 8b, which fixes an issue in the selectivity mirroring, and
1724 8c, which additionally fixes the last year of bias adjustment to 2019 and not 2020.
1725 With natural mortality fixed at 0.193, the growth parameter k is estimated at 0.114.
1726 The estimate of length at age-2 (L1) is 13.37, similar to the external estimates.

1727 **Request No. 9: Mirror the DebWV_CPFV selectivity to the RecN selec-
1728 tivity. Fix the start logit parameter for the adult PISCO selectivity to
1729 zero. Investigate appropriate methods for modeling selectivity for CCFRP.**

1731 **Rationale:** These will result in more appropriate and parsimonious treatment of se-
1732 lectivity.

1733 **STAT Response:** The selectivity for the CCFRP index was also mirrored to the
1734 Recreational North fleet since the length compositions were not drastically different
1735 than the other fleets mirrored to the Recreational North fleet. The STAT could not
1736 find a domed selectivity pattern that had reasonable parameter estimates.

1737 **Request No. 10: Perform a drop one out analysis for the index fleets.**

1739 **Rationale:** To investigate the influence each of these data sets on the model.

1740 **STAT Response:** No single index had a substantial effect on the model output. Each
1741 index contributed to the status of the stock, with some indicating a an increase over
1742 the base model developed for Request 9, and some estimating a decreased stock status.
1743 Depending on which index was dropped, the year(s) of high recruitment predicted in
1744 the early 1990s did shift, and was either attributed to a single year, or spread over a
1745 few years. The PISCO age-0 index does inform recruitment and age-0 recruitment is
1746 dampened n recent years when this index is excluded.

1747 **2.6 Post-STAR Base Case Model Results**

post-star-base-case-model-results

1748 The following description of the model results reflects a base model that incorporates all
1749 of the changes made during the STAR panel. A comparison of the pre-STAR base model
1750 and the post-STAR base model can be found in Figures 46, 47, and 48 and Table 24. A
1751 number of changes to the fleet structures, removal of surveys south of Point Conception, and
1752 the splitting of the PISCO index into two indices to better reflect life stages contributed to
1753 the changes. The final model also fixes natural mortality, whereas it was estimated in the
1754 pre-STAR base model. The pre-STAR base model includes an ageing error matrix that
1755 was developed using only half of the available double reads. The post-STAR base includes
1756 the updated ageing error matrix (Figure 49), and the update did not significantly change
1757 the model outputs. The remainder of the document referencing the base model (or base case)
1758 refers to the post-STAR base model.

1759 The base model parameter estimates and their approximate asymptotic standard errors are
1760 shown in Table 26 and the likelihood components are in Table 28. Estimates of derived
1761 reference points and approximate 95% asymptotic confidence intervals are shown in Table e.
1762 Time-series of estimated stock size over time are shown in Table 29.

1763 Steepness of the assumed Beverton-Holt stock-recruitment relationship was fixed at 0.72,
1764 and natural mortality was fixed at 0.193.

1765 **2.6.1 Convergence**

convergence

1766 Model convergence was determined by starting the minimization process from dispersed val-
1767 ues of the maximum likelihood estimates to determine if the model found a better minimum.
1768 Jitter is a SS option that generates random starting values from a normal distribution lo-
1769 gistically transformed into each parameter's range (Methot et al. 2019). This was repeated
1770 300 times and the minimum was reached in 67% of the runs (Table 25). The model did not
1771 experience convergence issues, e.g., final gradient was below 0.0001, when reasonable starting
1772 values were used and there were no difficulties in inverting the Hessian to obtain estimates of
1773 variability. We did sensitivity runs for convergence by changing the phases for key estimated
1774 parameters; neither the total log-likelihood nor the parameter estimates changed.

1775 **2.6.2 Parameter Estimates**

parameter-estimates

1776 The base model produces estimates of growth parameters different from the external esti-
1777 mates (Figure 50). The external estimate of the von Bertalanffy growth coefficient k was
1778 0.247, whereas the internal estimate was much lower at 0.107. Using the Schnute param-
1779 eterization with the age for L1 set at 2 and L2 at 23, the external estimates of lengths at
1780 Amin and Amax were similar at 13.80 and 28.22, respectively. The internal estimates of the

lengths for Amin and Amax were 13.4 and 28.80, respectively. Given that natural mortality was fixed in the base model and natural mortality and the growth parameter k are negatively correlated, the model estimated a slower rate of growth. A number of other factors including the length composition and selectivity affect the internal estimate of growth. Hence, growth was chosen as the axis of uncertainty for the decision table.

The estimated selectivities for all fleets within the model are shown in Figure 51. The selectivity curves for the commercial fleet, recreational fleets north and south of Point Conception, and the larger PISCO (15+ cm) were estimated. All of the selectivities are asymptotic except for the PISCO age-0 index, which has an age selectivity set to 1.0. All of the recreational indices and the CCFRP index selectivities were mirrored to the recreational fleet north of Point Conception. Attempts to fit asymptotic and dome-shaped selectivity to the CCFRP data resulted in poor estimation, large standard deviations, or a lack of fit to the data. The aggregated CCFRP length composition over time was similar to the length composition data of the recreational fleets north of Point Conception and mirroring the CCFRP selectivity provided a more parsimonious model. The recreational fleet south of Point Conception encounters smaller GBYR, which is reflected in the asymptotic selectivity shifted to the left of all other fleets. Selectivities for the recreational fleet north of Point Conception and the commercial fleet are very similar. Both fleets include both length composition of retained and discarded fish, although no information on the size of discards is available from the commercial fleet prior to 2004. The selectivity for the commercial fleet was kept separate because the fleet has different fishing behavior than the recreational fleet and going forward in time, may diverge further from the fleets depending on management decisions or changes in fishing behavior. Selectivity for the PISCO (15+ cm fish) index was estimated as the survey observes a wider range of length classes than the other fleets. The estimated peak of the PISCO selectivity hit the upper bound of 38 and was fixed at 38 in the base model. The age selectivity for the PISCO age-0 index was fixed at 1.0 and assumes that all age-0 fish are selected.

The additional survey variability (process error added directly to each year's input variability) for all surveys except the recreational dockside index north of Point Conception (RecDocksideNorth) and the PISCO age-0 index, was estimated within the model. The added variance for Deb's onboard observer survey was estimated at 0.06. The added variances were highest for the recreational onboard observer survey north of Point Conception (0.237) PISCO (0.152), and CCFRP (0.212).

Recruitment deviations were estimated from 1978-2018 (Figure 52). Estimates of recruitment suggest that GBYR are characterized by cyclical years of high and low recruitment (Figure 53). The final base model does not include early recruitment deviation and a steep bias adjustment ramp from 1978 to 1979 of 0.32 that extends to 2019 Figure 54. The years of highest estimated recruitment is 1991, with recruitment estimated more than double that of any other year.

Fish from this cohort can be observed in the length composition data from Deb Wilson Vandenberg's onboard observer survey and recreational fleet north of Point Conception in the later half of the 1990s. Additional periodic recruitment events are estimated from 1994

1823 and onward, with the peaks from 2001 and on driven by the PISCO age-0 index. followed by
1824 a period of below average recruitment, and another high recruitment pulse in the late 2010s.

1825 The stock-recruit curve resulting from a fixed value of steepness is shown in Figure 55.
1826 The stock has not been depleted to a low enough level that would inform the estimation of
1827 steepness. Steepness was not estimated in this model, and profiles over steepness values are
1828 discussed below.

1829 2.6.3 Fits to the Data

fits-to-the-data

1830 Model fits to the indices of abundance, fishery length composition, survey length composition,
1831 and conditional age-at-length observations are all discussed below. The full r4ss plotting
1832 output is available in the supplementary material.

1833 The fits to the three fishery-dependent and three fishery-independent survey indices are
1834 shown in Figures 56, 57, 58, 59, 60, and 61. All indices represent the area north of Point
1835 Conception only, and not all of these were fit well by the assessment model. The MRFSS
1836 CPFV recreational dockside survey index north of Point Conception spanning the 1980s-
1837 1990s was fit well by the model without added variance, but relatively flat, and is not a very
1838 informative index. The index for Deb Wilson-Vandenberg's CPFV onboard observer survey
1839 spanning 1988-1998 was well fit and indicates an increase in relative abundance in the last
1840 year of the survey. The current recreational CRFS/Cal Poly onboard observer survey north
1841 of Point Conception from 2001-2018 was relatively well fit, except for the decline suggested
1842 2013 and 2014. The increase in relative abundance observed in 2018 was not fit by the
1843 model, even with the added variance. The variance added to this survey was the highest for
1844 all indices.

1845 The model did not capture the contrast in the PISCO index for 15+ cm fish, fitting a decline
1846 to the time series from 2010 to 2018, when the index suggests an increase from 2010 to 2013
1847 and another increase after a decline in 2016. The model does capture the PISCO age-0 index
1848 without added variance. A number of years, e.g., 2004-2008, were marked by low relative
1849 abundance of age-0 GBYR and have larger standard errors. The years with lower relative
1850 abundance were not captured by the model, but fit to the upper bound of the input standard
1851 error. The increases in age-0 GBYR in 2001, 2001, 2014-2015 and 2017 were captured in the
1852 model fit.

1853 The model was not able to capture the trends observed in the fishery-independent CCFRP
1854 hook-and-line survey. The index suggested the same depressed relative abundance in 2013 as
1855 the fishery-dependent CRFS/Cal Poly onboard observer survey, that was also not captured
1856 here by the fit. The increasing trends in abundance from 2016-2018 was also not captured
1857 by the model fit, and the fit suggests a declining trend over the entire time series from
1858 2007-2018.

1859 The base model was re-weighted twice using Francis weights for the length and age composition data. Fits to the length data are shown based on the proportions of lengths observed
1860 by year and the Pearson residuals-at-length for all fleets. Detailed fits to the length data
1861 by year and fleet are provided in Appendix 8. Aggregate fits by fleet are shown in Figure
1862 62. Overall, the length composition all fit well. The PISCO fleet has the noisiest of all the
1863 length composition data, but on an annual basis, the length data were relatively well fit.
1864 The fit to the aggregated CCFRP data suggests the model expects to see additional larger
1865 fish, which is likely due to the mirroring of the selectivity. However, on an annual basis,
1866 there is a trade-off with the CCFRP with under-fitting of the larger fish in the earlier years
1867 and an under-fitting of the smaller fish expected in the later years (2013-2018).

1869 The mean age of the recreational fleet varied from 1980-1986 ranging from approximately
1870 8-11, and increased in 2017 to approximately 13 (Figure 63). The conditional age data from
1871 the CCFRP data was not well fit for the earliest years in the data, but was reasonably well
1872 fit for the last four years of data (Figure 64). The conditional length composition data from
1873 the ‘dummy’ fleet was well fit, although heavily down-weighted. Age data in this fleet are
1874 from a number of sources and sampling programs (Figure 65).

1875 2.6.4 Retrospective Analysis

retrospective-analysis

1876 A 4-year retrospective analysis was conducted by running the model using data only through
1877 2017 (retro 1), 2016 (retro 2), 2015 (retro 3), and 2014 (retro 4) (Table 30). The initial popu-
1878 lation size and estimation of trends in spawning biomass in the retrospective runs were lower
1879 than the base model, except for retro 1 (Figure 66). All retrospective runs followed the same
1880 general trend, with the differences in the trends stemming from the change in recruitment
1881 deviations (Figure 67). The PISCO age-0 index has a signal of increased recruitment in
1882 the most recent years. For Retro2, Retro3, and Retro4, the trends in recruitment are not
1883 observed by the model. There is no conditional age-at-length composition data for 2015-
1884 2016, leading to the minor change in the age composition likelihood from Retro2 to Retro3
1885 and Retro4 (Table 30). The age composition data in 2017 accounts for 2.5% of all available
1886 ages, and 4.5% of all fish aged were from 2018. The available length data in each year from
1887 2015-2018 range from 4-6% of the total available length data. The length compositions of all
1888 the other fleets have similar length distributions for 2015-2018 (8). Additional investigations
1889 into the retrospective patters will be made by the STAT.

1890 2.6.5 Likelihood Profiles

likelihood-profiles

1891 Likelihood profiles were conducted for R_0 , steepness, and over natural mortality values sep-
1892 arately with the post-STAR base. These likelihood profiles were conducted by fixing the
1893 parameter at specific values and estimated the remaining parameters based on the fixed
1894 parameter value (Tables 31-32).

1895 In regards to values of R_0 , the negative log-likelihood was minimized at approximately
1896 $\log(R_0)$ of 8.0 (Table 31 and Figure 70). In terms of likelihood components, only the index
1897 data minimize at the upper bound, while the other components minimize between 8.0 and
1898 8.1. The individual surveys tend to minimize at the upper bound or just below, while the
1899 length composition data has conflicting trends, e.g., CCFRP and commercial fleets minimize
1900 at the upper bound while the recreational north fleet minimizes at the lower bound (Figures
1901 68-69). The majorityd ata all consistently minimize around 8. Over the range of values of
1902 R_0 , depletion ranged from 0.38-0.59 (Figure 71).

1903 For steepness, the negative log-likelihood reaches a minimum around a steepness near the
1904 upper bound of 1.0 (Figure 74 and Table 31 and Figure 79). The length composition like-
1905 lihood components declined towards the upper bound for Deb's onboard CPFV survey and
1906 the recreational north fleet, while the other fleets either reached a minimum around 0.55 or
1907 at the lower bound (Figure 72). Overall changes in the survey likelihood across the range
1908 of steepens was less than 2.0, with surveys either minimized at the lower or upper bound
1909 (Figure 73). The relative depletion for GBYR ranges from 0.375 to 0.493 across different
1910 assumed values of steepness (Table 31).

1911 The negative log-likelihood was minimized at a natural mortality value around 0.21, slightly
1912 higher than the prior of 0.193 (Table 31 and Figure 78). The age, length, index, and prior
1913 likelihood contributions were minimized at natural mortality values around 0.22, and the
1914 recruitment contribution was minimized at the upper bound. (Table 31). The length compo-
1915 sition minimizes around a natural mortality value of 0.14, with the commercial, recreational
1916 fleet north of Point Conception, and CCFRP data minimizing towards the lower bound (Figure
1917 76). The length data from Deb's CPFV survey minimizes around 0.22, while the PISCO and
1918 recreational length compositions south of Point Conception minimize at the upper bound.
1919 The PISCO and CCFRP surveys minimized around a natural mortality value of 0.22, while
1920 the PISCO age-0 and overall survey likelihood minimized at the upper bound of 0.3 (Figure
1921 77). The relative depletion for GBYR ranged from 0.32-0.59 across alternative values of
1922 natural mortality (Figure 79).

1923 2.6.6 Reference Points

reference-points-1

1924 Reference points were calculated using the estimated selectivities and catch distribution
1925 among fleets in the most recent year of the model, (2017). Sustainable total yield (landings
1926 plus discards) were 134 mt when using an $SPR_{50\%}$ reference harvest rate and with a 95%
1927 confidence interval of 116 mt based on estimates of uncertainty. The spawning biomass
1928 equivalent to 40% of the unfished level ($SB_{40\%}$) was 504 mt.

1929 The predicted spawning output from the base model shows an initial decline starting the
1930 1950s, is then stable, and declines steeply until 1995 (Figure 80). The spawning output then
1931 rapidly increases through the early 2000s, and has been in a decline since 2006.

1932 The 2018 spawning biomass relative to unfished equilibrium spawning biomass is above the
1933 target of 40% of unfished levels (Figure 81). The relative fishing intensity, $(1 - SPR)/(1 - SPR_{50\%})$, was below the management target from 1981-1998, and below the minimum stock
1934 size threshold in 1995. The stock has been above the management target since 1999.
1935

1936 Table e shows the full suite of estimated reference points for the base model and Figure 82
1937 shows the equilibrium curve based on a steepness value fixed at 0.72.

1938 3 Harvest Projections and Decision Tables

harvest-projections-and-decision-tables

1939 This section will be copied from the Executive Summary once decision tables are finalized
1940 after the groundfish SSC meeting in August 2019.

1941 4 Regional Management Considerations

regional-management-considerations

1942 While the proportion of the stock residing within U.S. waters is unknown, the assessment
1943 provides an adequate geographic representation of the portion assessed for management
1944 purposes. There is little evidence that black-and-yellow rockfish extend into Mexico, and
1945 the proportion of gopher rockfish residing south of Pt. Conception is small. While there has
1946 been work on the genetic structure between the two species, there has not been work done
1947 within each species to inform spatial structure of the populations. Given the relatively small
1948 area in the waters of California where these species occur, there is relatively little concern
1949 regarding exploitation in proportion to the regional distribution of abundance in the area
1950 assessed in this study.

1951 The state of California implements regional management for the recreational fleet in the form
1952 of five regions, referred to as management areas with differing depth and season restrictions.
1953 Neither gopher nor black-and-yellow rockfish are a large component of the total recreational
1954 landings and are managed as part of the
1955 nearshore rockfish complex. Current regional management appears appropriate for these
1956 species.

1957 5 Research Needs

research-needs

1958 This section will be copied from the Executive Summary after further discussions.

1959 **6 Acknowledgments**

acknowledgments

1960 We gratefully acknowledge input and review from the STAR panel including the Owen
1961 Hamel (STAR panel chair; Northwest Fisheries Science Center, NMFS, NOAA), Chantel
1962 Wetzel(Northwest Fisheries Science Center, NMFS, NOAA), Sven Kupschus (Center for
1963 Independent Experts), and Robin Cook (Center for Independent Experts). Thanks to Don
1964 Pearson for reading all of the gopher and black-and-yellow rockfish before retiring in 2018.
1965 We thank John Field, John Budrick, Rebecca Miller, and Emma Saas for contributions to the
1966 assessment document. A special thanks to the PISCO and CCFRP programs for conducting
1967 and providing the available fishery-independent data used in the assessment. Thank you
1968 to everyone who answered my countless emails regarding your survey methodologies and
1969 datasets.

Table 7: Data filtering steps for Deb Wilson-Vandenberg's CPFV onboard observer index of abundance

Filter	tab:Fleet5_Filter	Drifts	Positive Drifts
Remove errors, missing data		6691	1470
Remove 1987 (sampled only MNT), 1990-1991 low sample sizes		4283	1372
Remove reefs that never encountered GBY		4022	1372
Remove lower and upper 2.5% of time fished		3762	1300
Remove depth less than 9 m and greater than 69 m		3515	1279
Remove reefs with low sample rates		2411	1096

Table 8: Model selection for Deb Wilson-Vandenberg's CPFV onboard observer index of abundance. Bold values indicate the model selected.

Model	Lognormal	Binomial	tab:Fleet5_AIC
Year	2834	3330	
Year + Depth	2781	2906	
Year + Reef	2716	2880	
Year + Month	2839	3286	
Year + Depth + Reef	2625	2488	
Year + Month+ Reef	2725	2844	
Year + Depth + Month	2780	2902	
Year+ Depth+Month+Reef	2632	2479	

Table 9: Data filtering steps for the CRFS CPFV onboard observer index of abundance for north and south of Pt. Conception.

Filter	Drifts	Positive Drifts	tab:Fleet6_7_Filter
Data from SQL filtered for missing data	67850	9317	
Remove years prior to 2001 and north of Cape Mendocino	64448	9129	
Depth, remove 1% data on each tail of positive catches	50846	8955	
Time fished, remove 1% data on each tail	50100	8903	
Observed anglers, remove 1% data on each tail	48089	8774	
Limit to reefs observering gopher/byel in at least 20 drifts	29639	8025	
Limit to reefs sampled in at least 2/3 of all years	32672	7517	
Limit to drifts within 1000 m of a reef	27355	7358	
Put depth in 10m depth bins, remove 0-9 and 60-69 m bins	25427	7250	
Start of north filtering	13792	6036	
Filter to drifts within 43 m of a reef, 97% quantile	13145	5854	
Make sure reefs still sampled at least 2/3 of years	12965	5796	
Start of south filtering	11635	1277	
Filter to drifts with $\geq 20\%$ groundfish and recheck reefs	5495	1171	
Make sure reefs still sampled at least 2/3 of years	5440	1132	

Table 10: Model selection for the CRFS CPFV onboard observer index of abundance for north of Pt. Conception. Bold values indicate the model selected.

Model	Lognormal	Binomial	tab:Fleet6_AIC
Year	14135	17531	
Year + Month	14120	17529	
Year + Depth	13953	17025	
Year + Reef	14126	17293	
Year + Month + Depth	13951	17027	
Year + Month + Depth + Reef	13921	16674	

Table 11: Model selection for the CRFS CPFV onboard observer index of abundance for south of Pt. Conception. Bold values indicate the model selected.

Model	Lognormal	Binomial	tab:Fleet7_AIC
Year	2798	5490	
Year + Month	2799	5487	
Year + Depth	2744	5159	
Year + Reef	2653	5390	
Year + Depth + Reef	2652	5071	
Year + Depth + Reef + Month	2663	5072	

Table 12: Data filtering steps for the PISCO dive survey.

Filter	Transects	Positive Transects	tab:Fleet8_Filter
Remove missing data and retain only bottom transects	22,055	6,330	
Remove month of June - few samples	21,941	6,318	
Remove dives earlier than 2004 for UCSB and 2001 for UCSC	20,659	6,165	
Keep sites sampled in at least half of all years (UCSC and UCSB separate)	14,721	4,097	
Keep sites observing GBYR in at least half of all years	12,139	4,002	
Remove transects denoted as old, no longer sampled	10,712	3,268	
Subset to just UCSC sites	5,686	2,939	
Use only consistently sampled sites	3,231	1,729	
Collapse repeated transects	1,928	1,487

₁₉₇₁ 8 Figures

figures

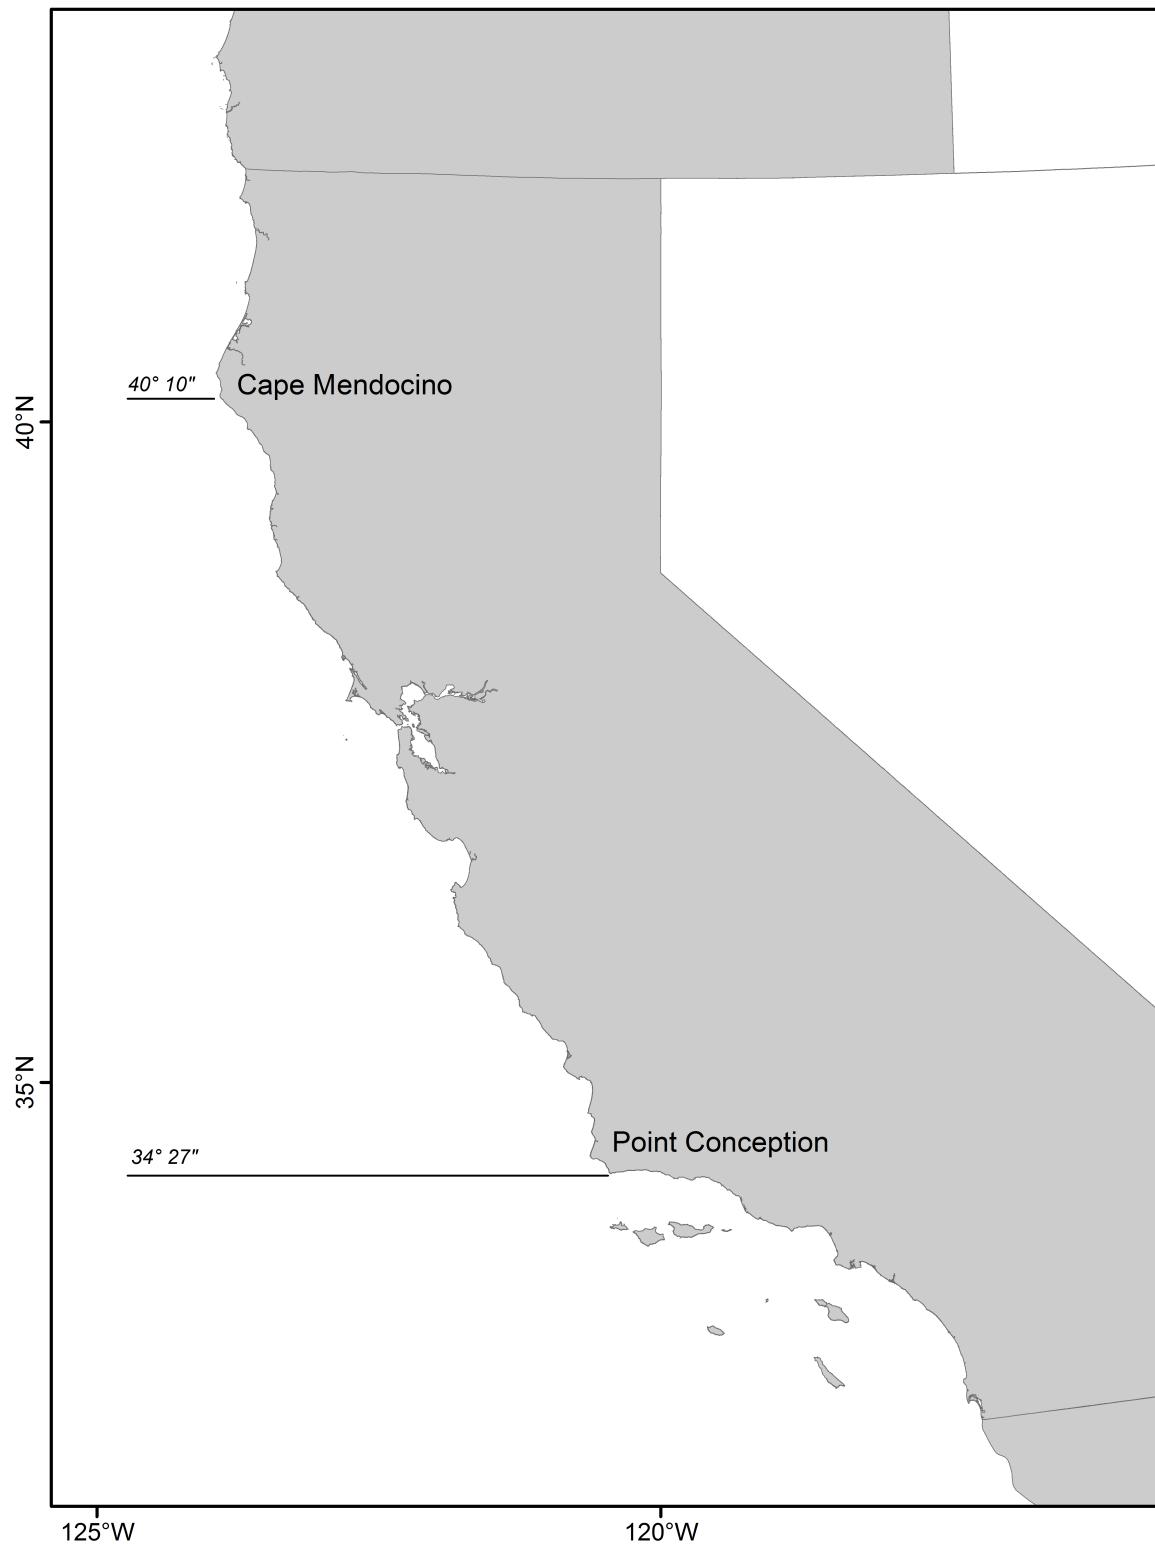

Figure 1: Map showing the management area for gopher and black-and-yellow rockfish from Cape Mendocino to the U.S.-Mexico border. fig:assess_region_map1

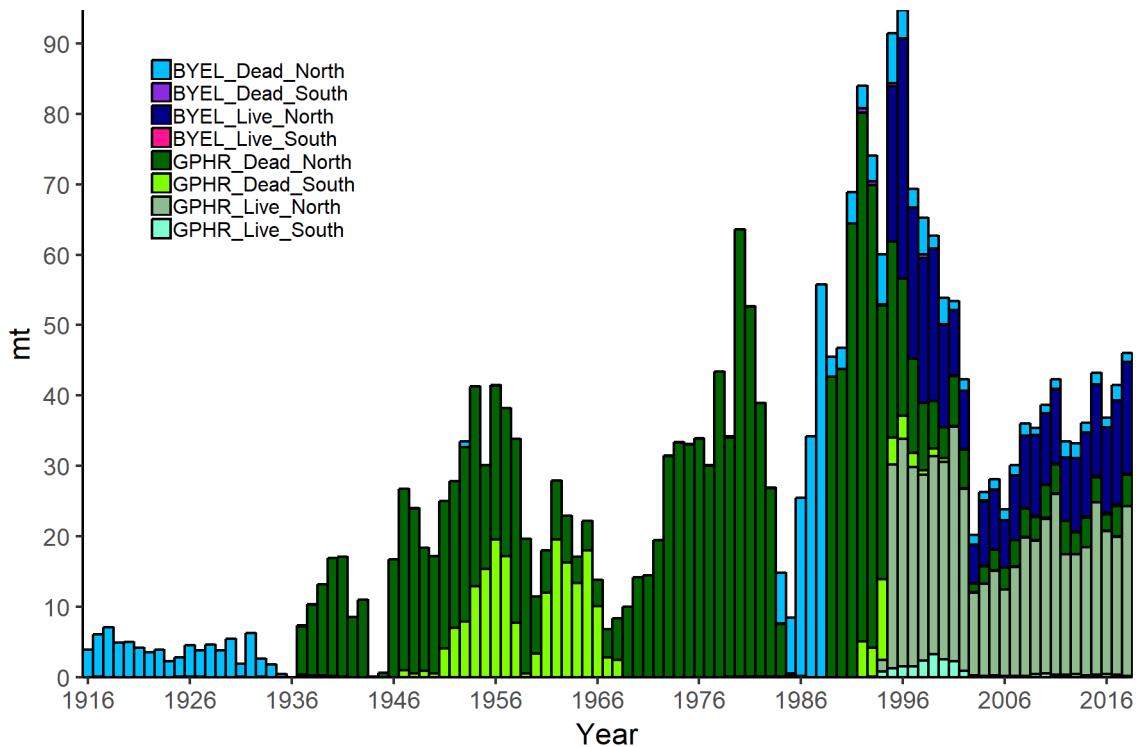

Figure 2: Commercial landings for gopher (GPHR) and black-and-yellow (BYEL) rockfishes landed live and dead north and south of Point Conception. All catch time series were combined for the assessment into one commercial fleet.

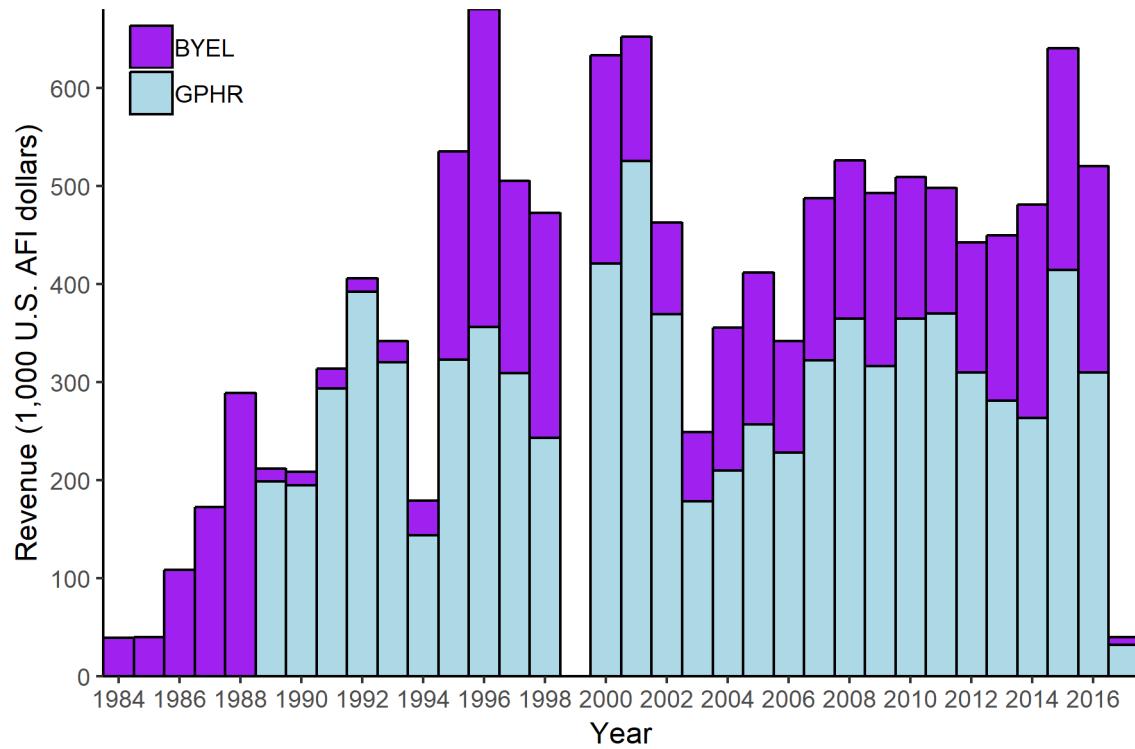

Figure 3: Annual ex-vessel revenue, adjusted for inflation (AFI) in thousands of dollars for gopher and black-and-yellow rockfish. [fig:GBY_revenue](#)

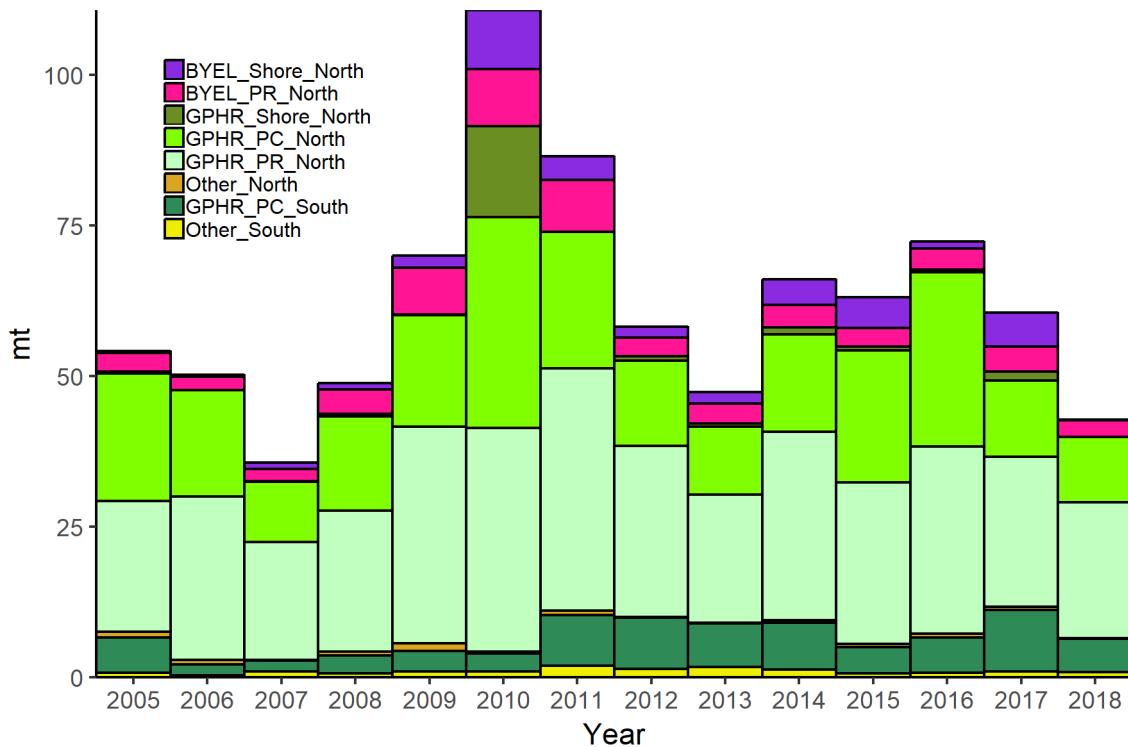

Figure 4: Recreational total mortality for gopher rockfish (GPHR) and black-and-yellow (BYEL) rockfish from the CDFW CRFS sampling era by mode and split north and south of Point Conception. fig:CFRS_catches

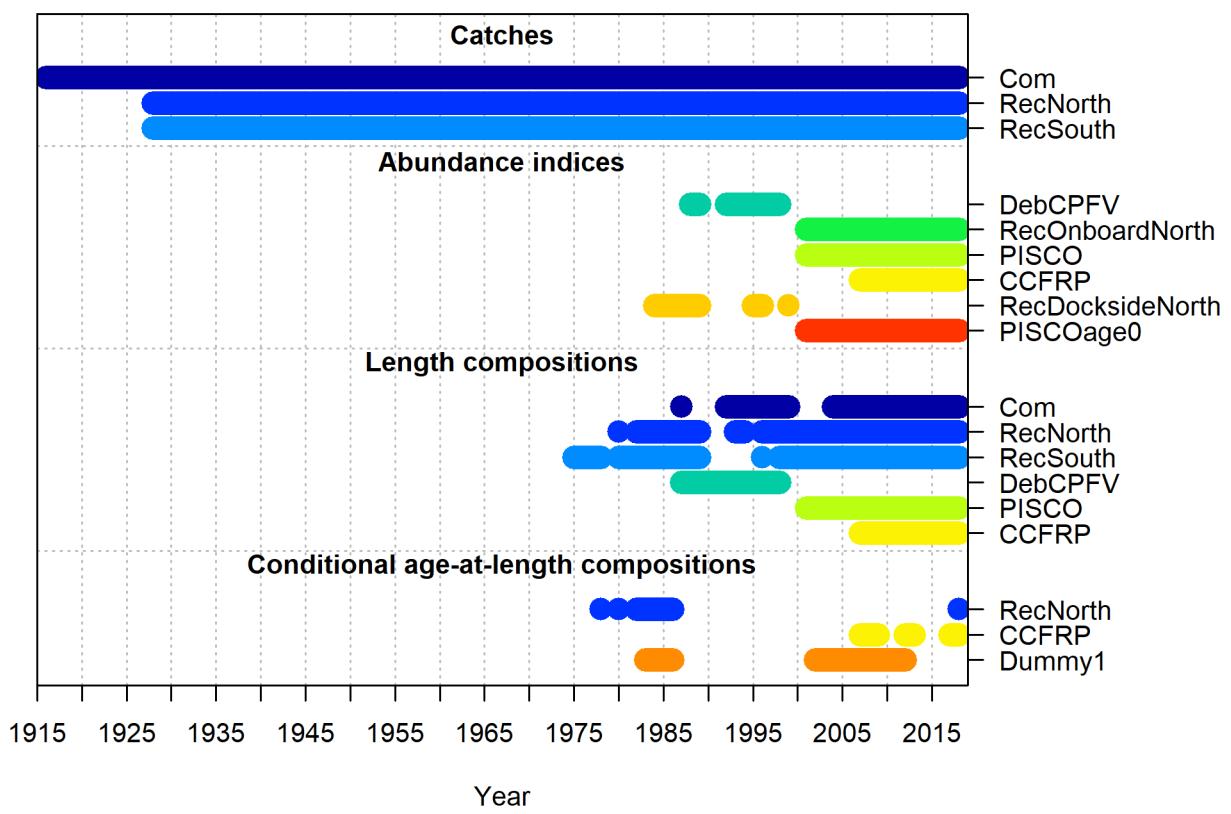

Figure 5: Summary of data sources used in the model. `fig: data_plot`

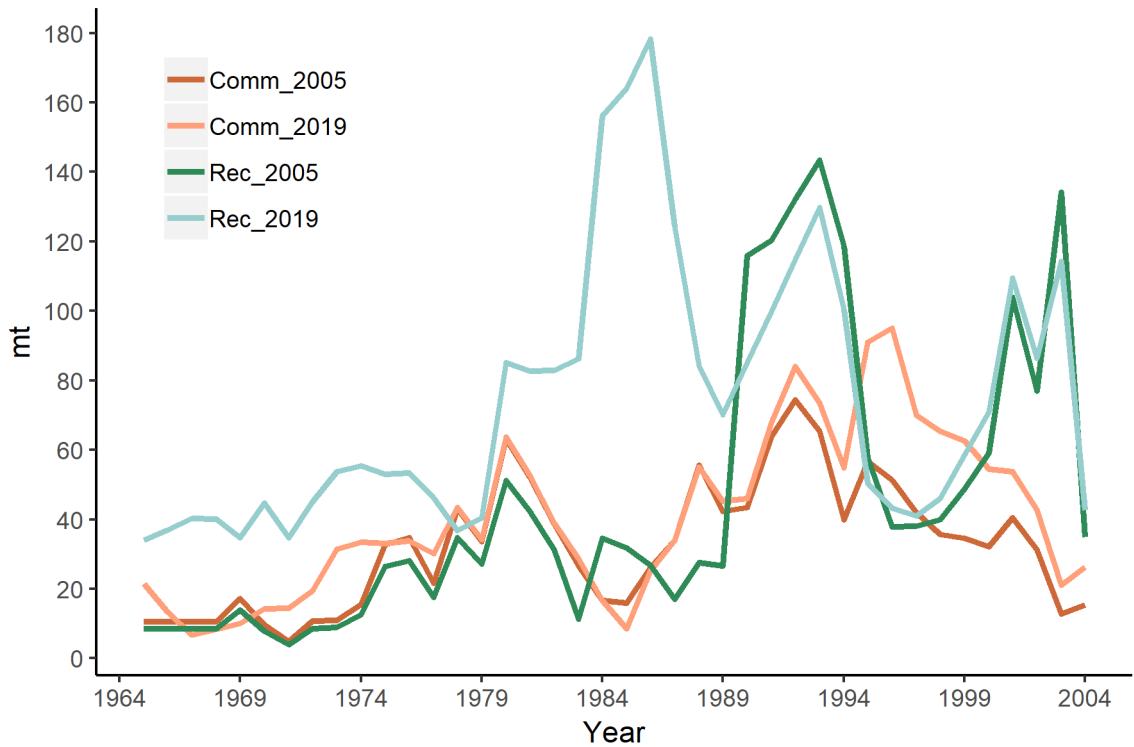

Figure 6: Comparison of the recreational and commercial fishery landings from the 2005 assessment to this 2019 assessment. Note that the 2019 assessment includes both gopher and black-and-yellow rockfish where the 2005 assessment represents gopher rockfish only. The 2005 assessment also did not include landings from south of Point Conception. | [fig:Assessment_comp](#)

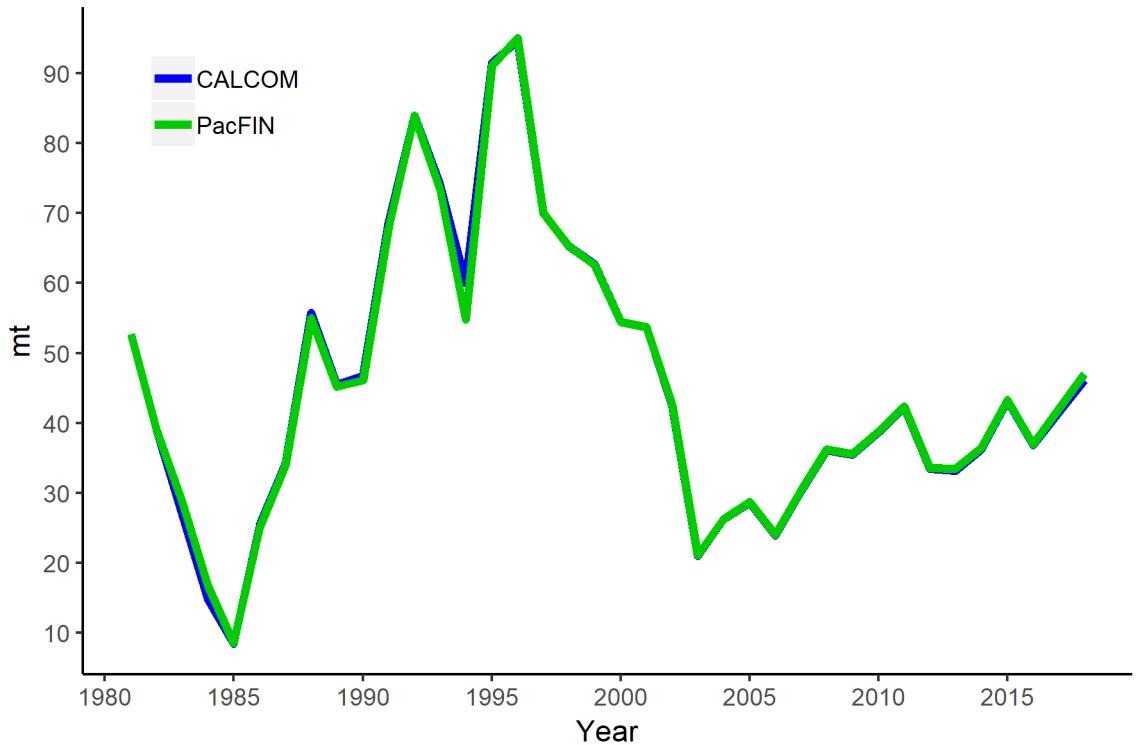

Figure 7: Commercial landings estimates from CALCOM and PacFIN. fig:Calcom_vs_Pacfin

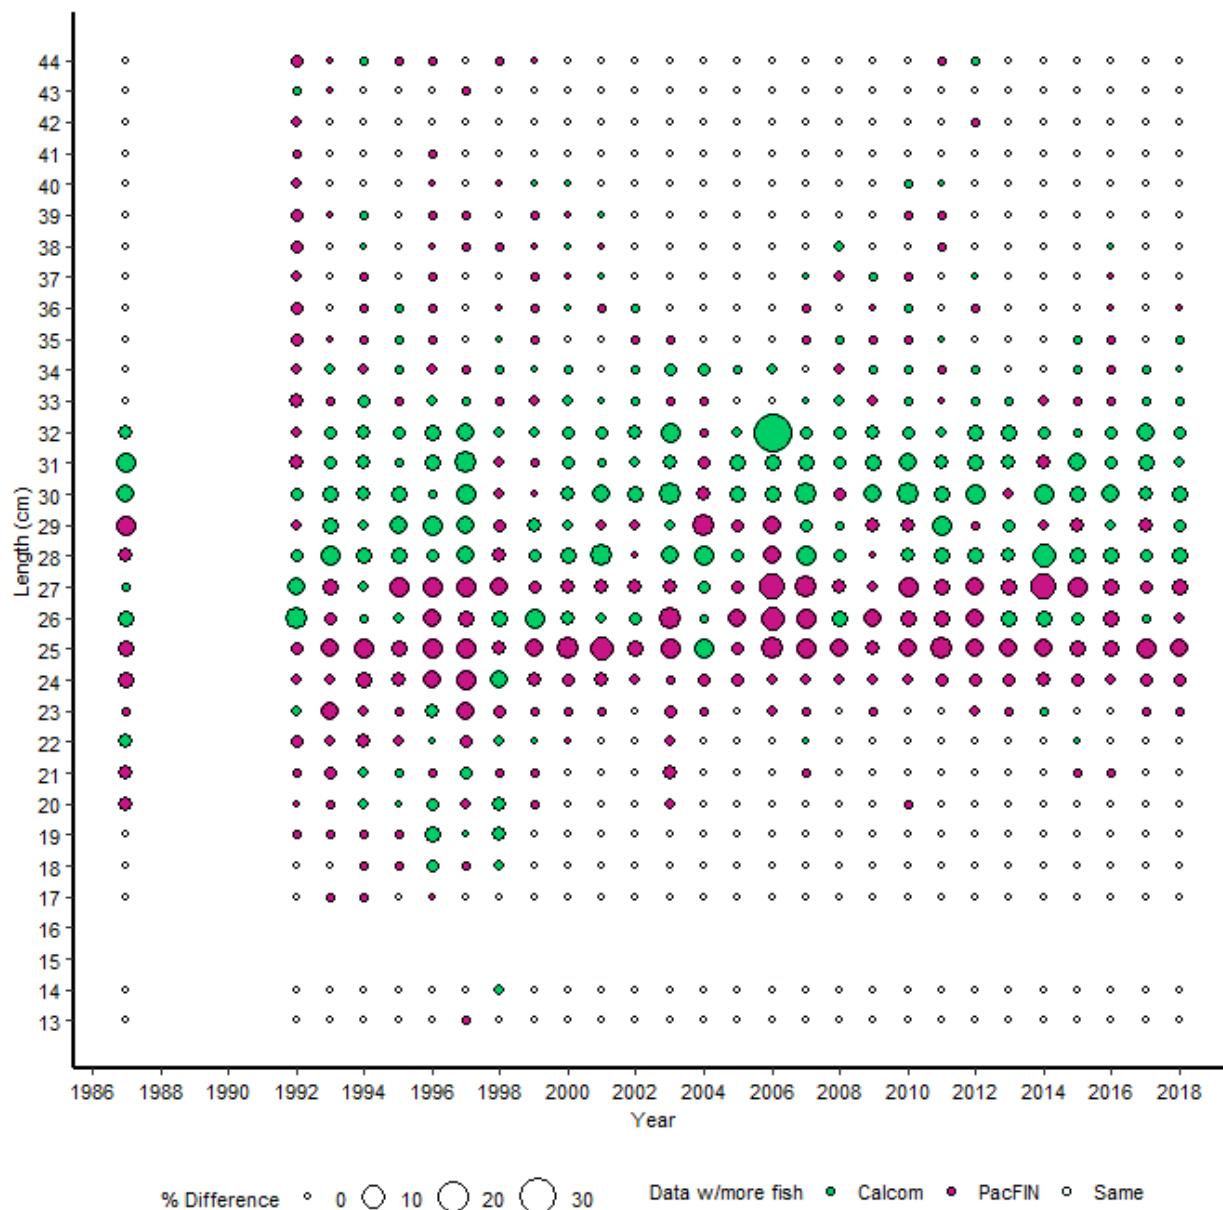

Figure 8: Percent differences in the expanded length compositions by year from CALCOM and PacFIN. The same market categories were used for each dataset, but each database was subject to further independent filtering criteria and expansion algorithms. fig:Calcom_vs_pacfin_length

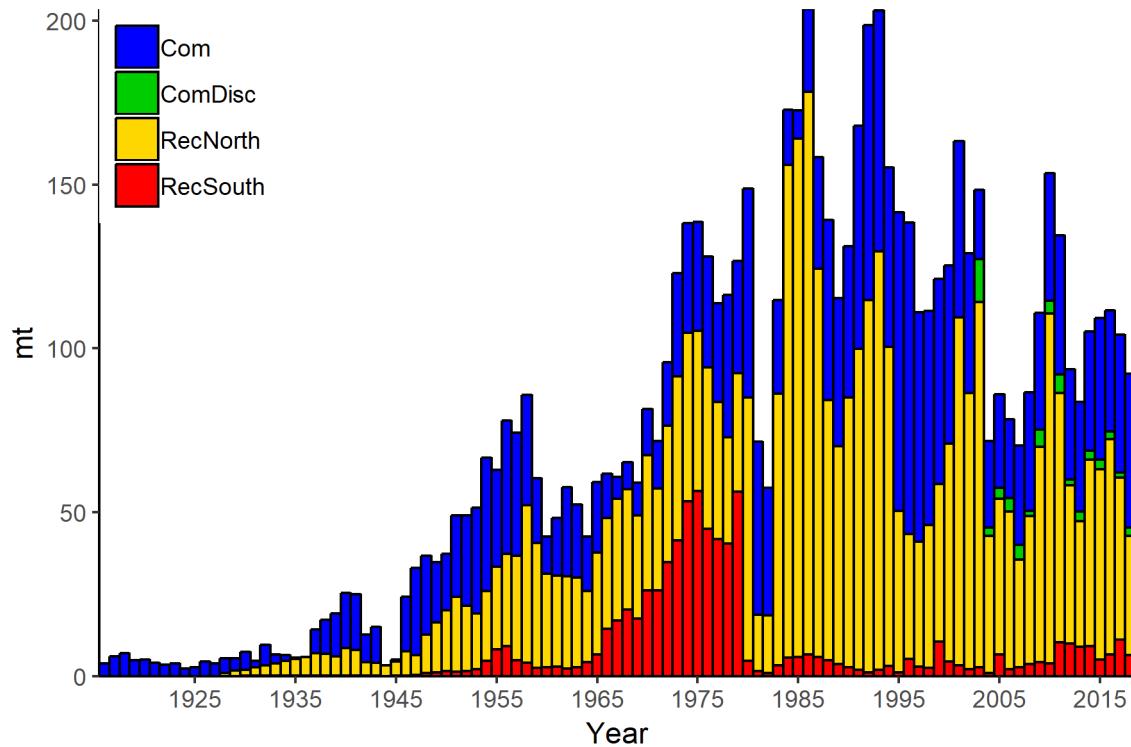

Figure 9: Commercial and recreational landings estimates prior to any data modification or interpolation to the recreational catches or hindcasting of commercial discards. [fig:Catches_original](#)

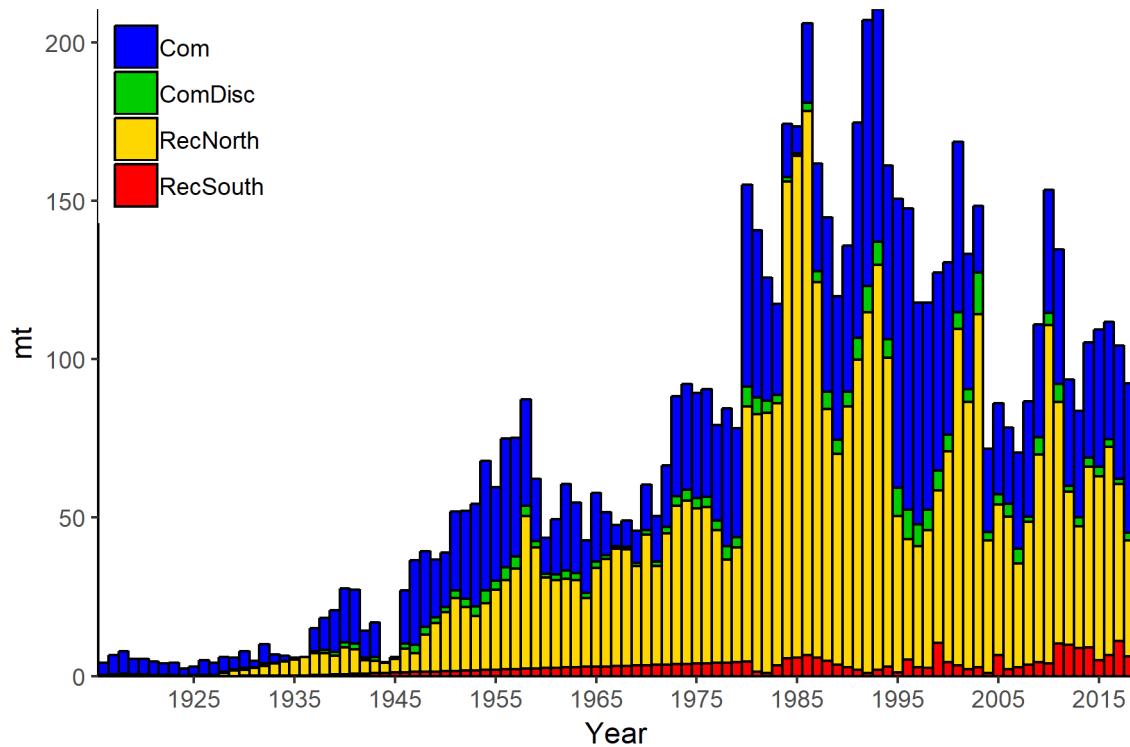

Figure 10: Commercial and recreational landings estimates after data modification and interpolations were made to the recreational catches and commercial discards. [fig:Catches_alternate](#)

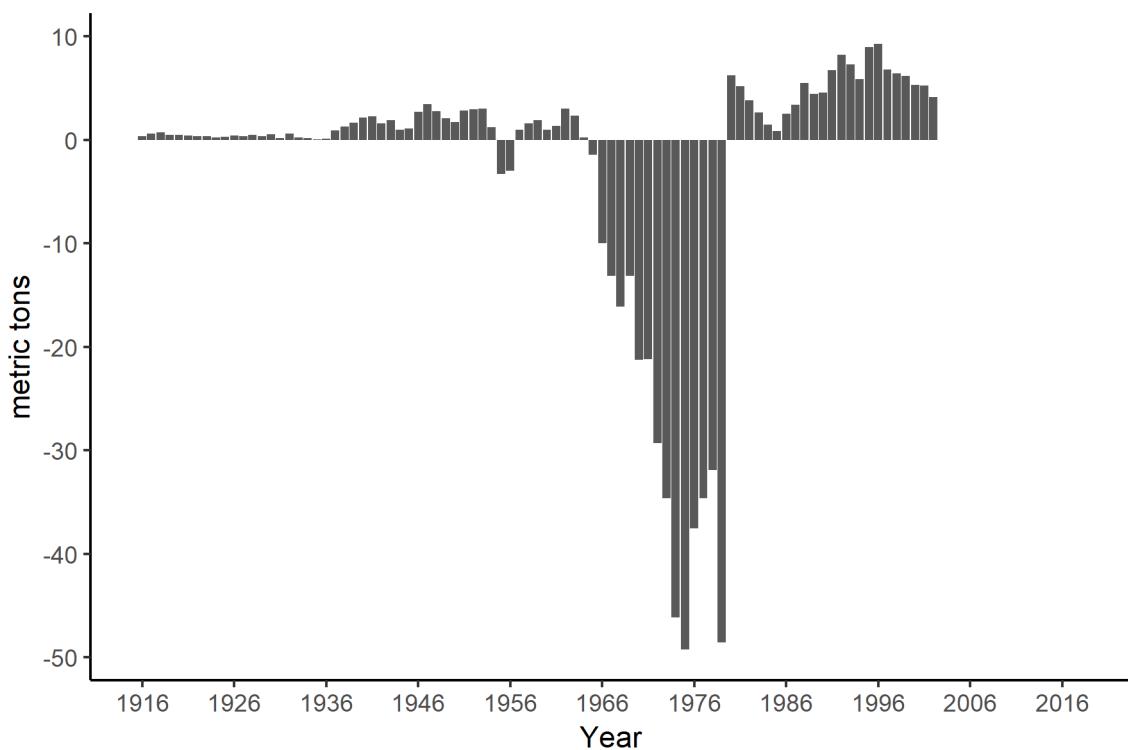

Figure 11: Difference in landings between the original and modified landings presented in the previous two figures. The only two fleets with modifications are recreational south and commercial discards. Negative values indicate catches removed from the original estimates and positive values represent the addition of landings from the commercial dicard fleet. fig:catches_diff

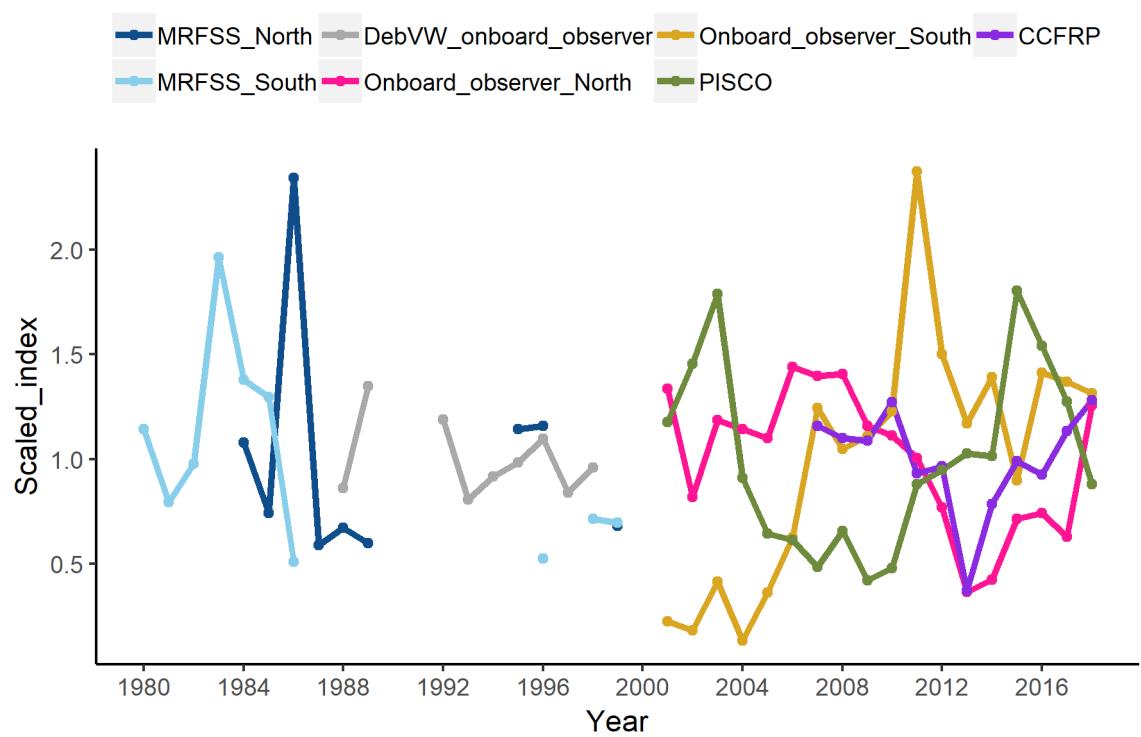

Figure 12: Comparison of all indices of abundance (with each index scaled to its mean). [fig:All_index](#)

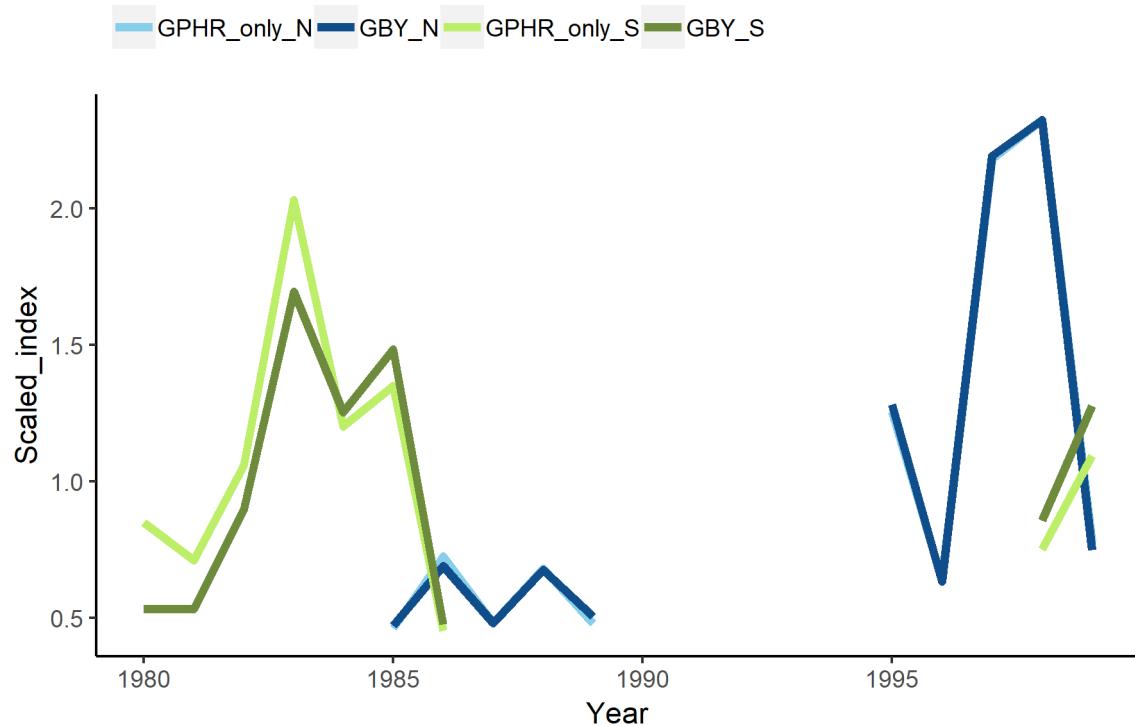

Figure 13: Comparison of indices of abundance (scaled to their means) for the MRFSS dockside CPFV survey between a gopher-only and GBYR complex index for north and south of Point Conception. [fig:MRFSS_index_compare](#)

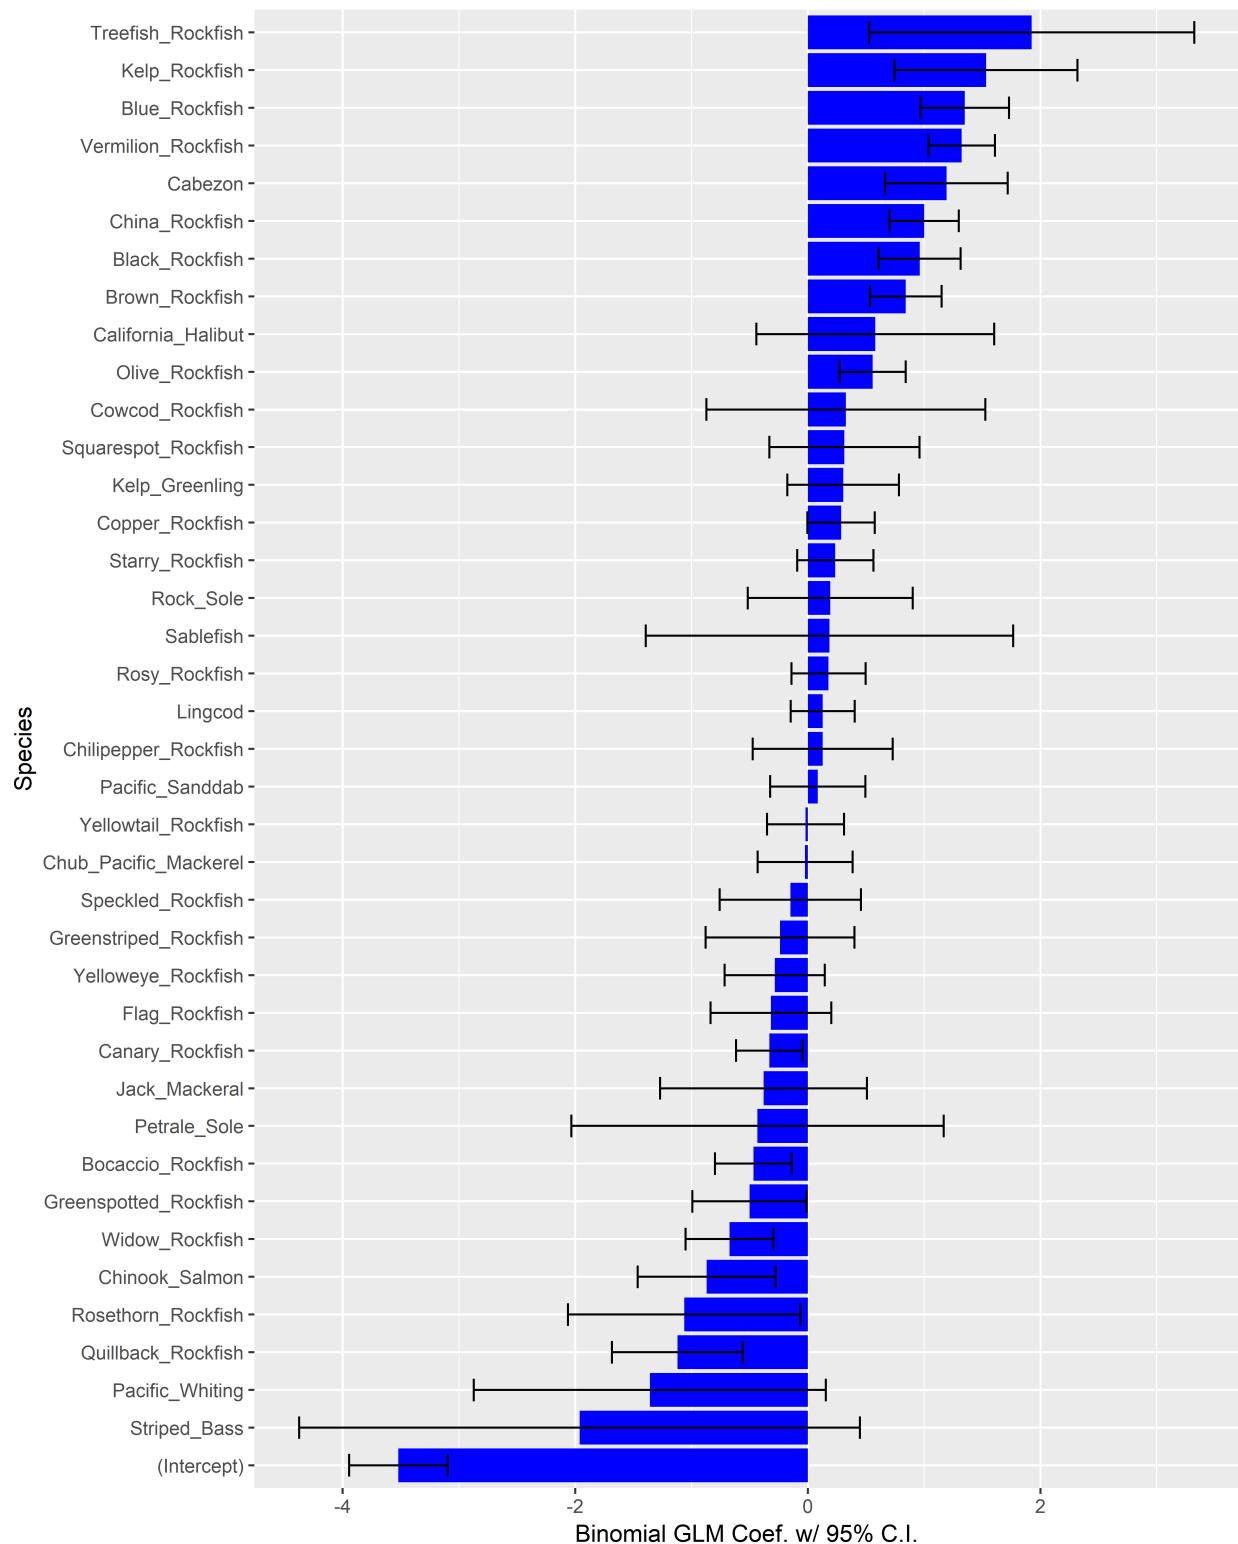

Figure 14: Species coefficients from the binomial GLM for presence/absence of GBYR in the Marine Recreational Fisheries Statistics Survey (MRFSS) CPFV mode dockside survey data set north of Point Conception. Horizontal bars are 95% confidence intervals. fig:Fleet10_SM_filter

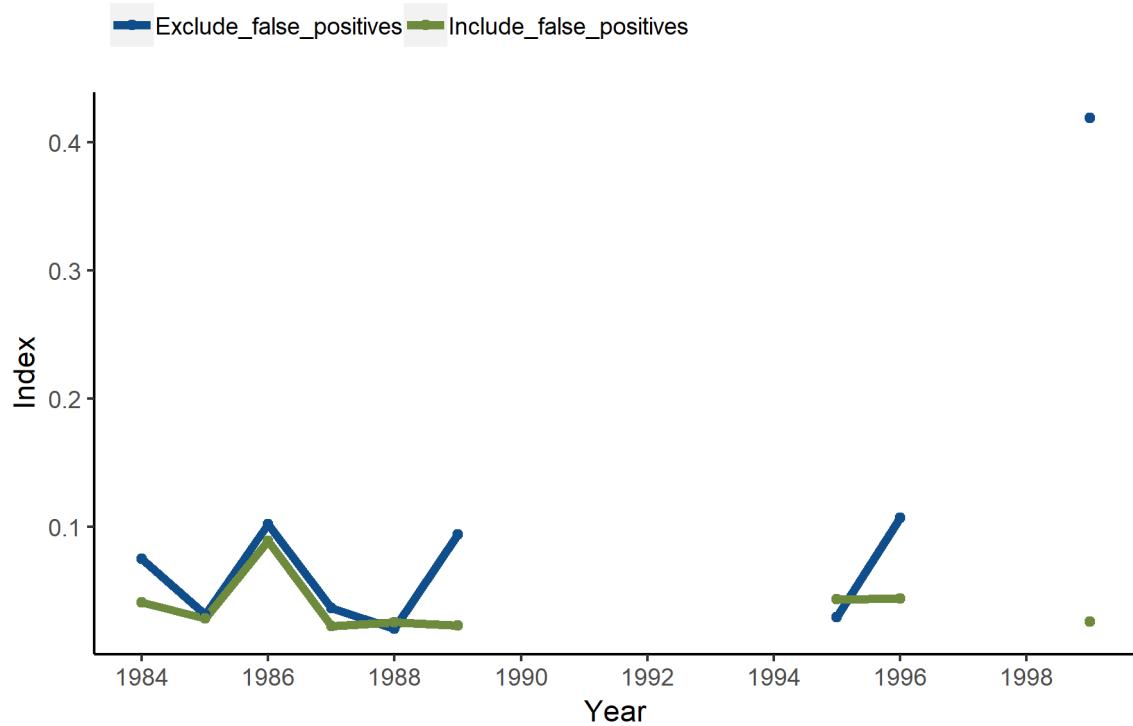

Figure 15: Comparisons of the indices of abundance for GBYR north of Point Conception from the MRFSS dockside CPFV survey that either include or exclude the trips identified as false positives from the Stephens-MacCall filter. [fig:MRFSS_index_N_SM_falsepos](#)

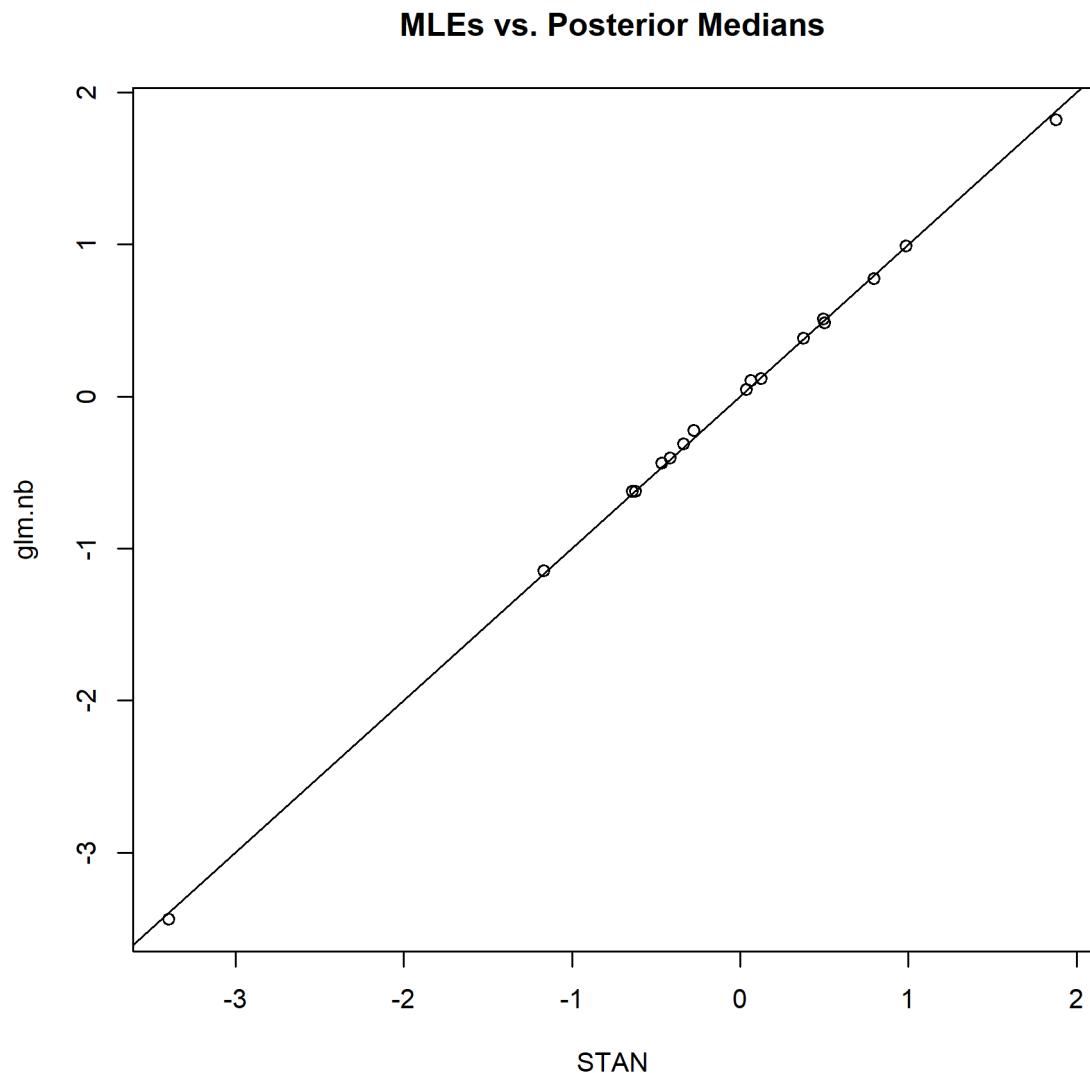

Figure 16: Comparison of negative binomial predictions (CPUE) to observed means in each stratum (year). MRFSS CPFV dockside index north of Point Conception. The 1:1 plot is for reference. [fig:Fleet10_MLE_stan](#)

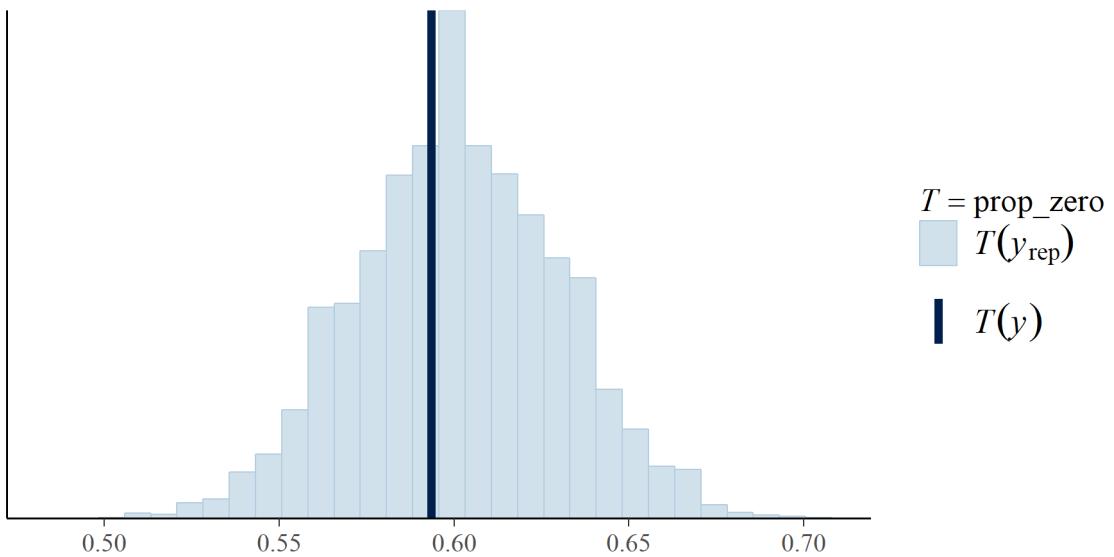

Figure 17: Posterior predictive distribution of the proportion of zero observations in replicate data sets generated by the negative binomial model for MRFSS dockside CPFV index north of Point Conception. `fig:Fleet10_prop_zero_STAN`

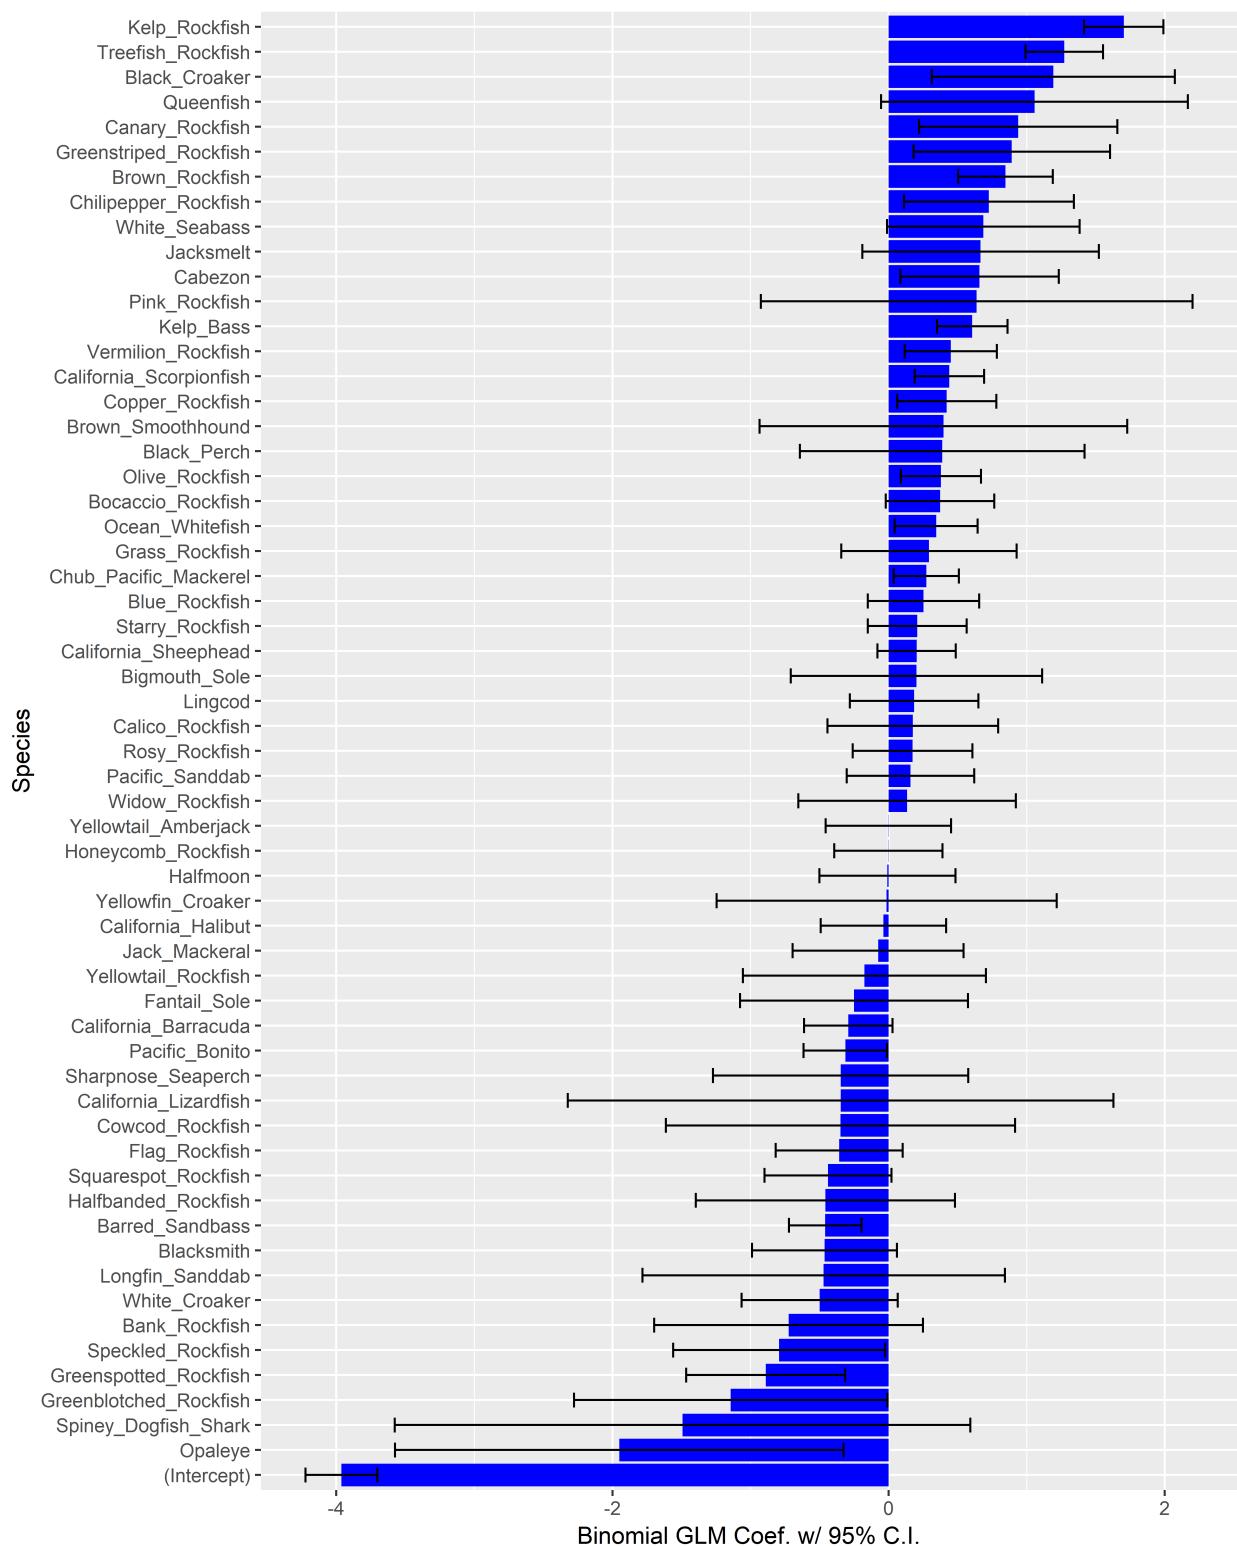

Figure 18: Species coefficients from the binomial GLM for presence/absence of GBYR in the Marine Recreational Fisheries Statistics Survey (MRFSS) CPFV mode dockside survey data set north of Point Conception. Horizontal bars are 95% confidence intervals. fig:Fleet11_SM_filter

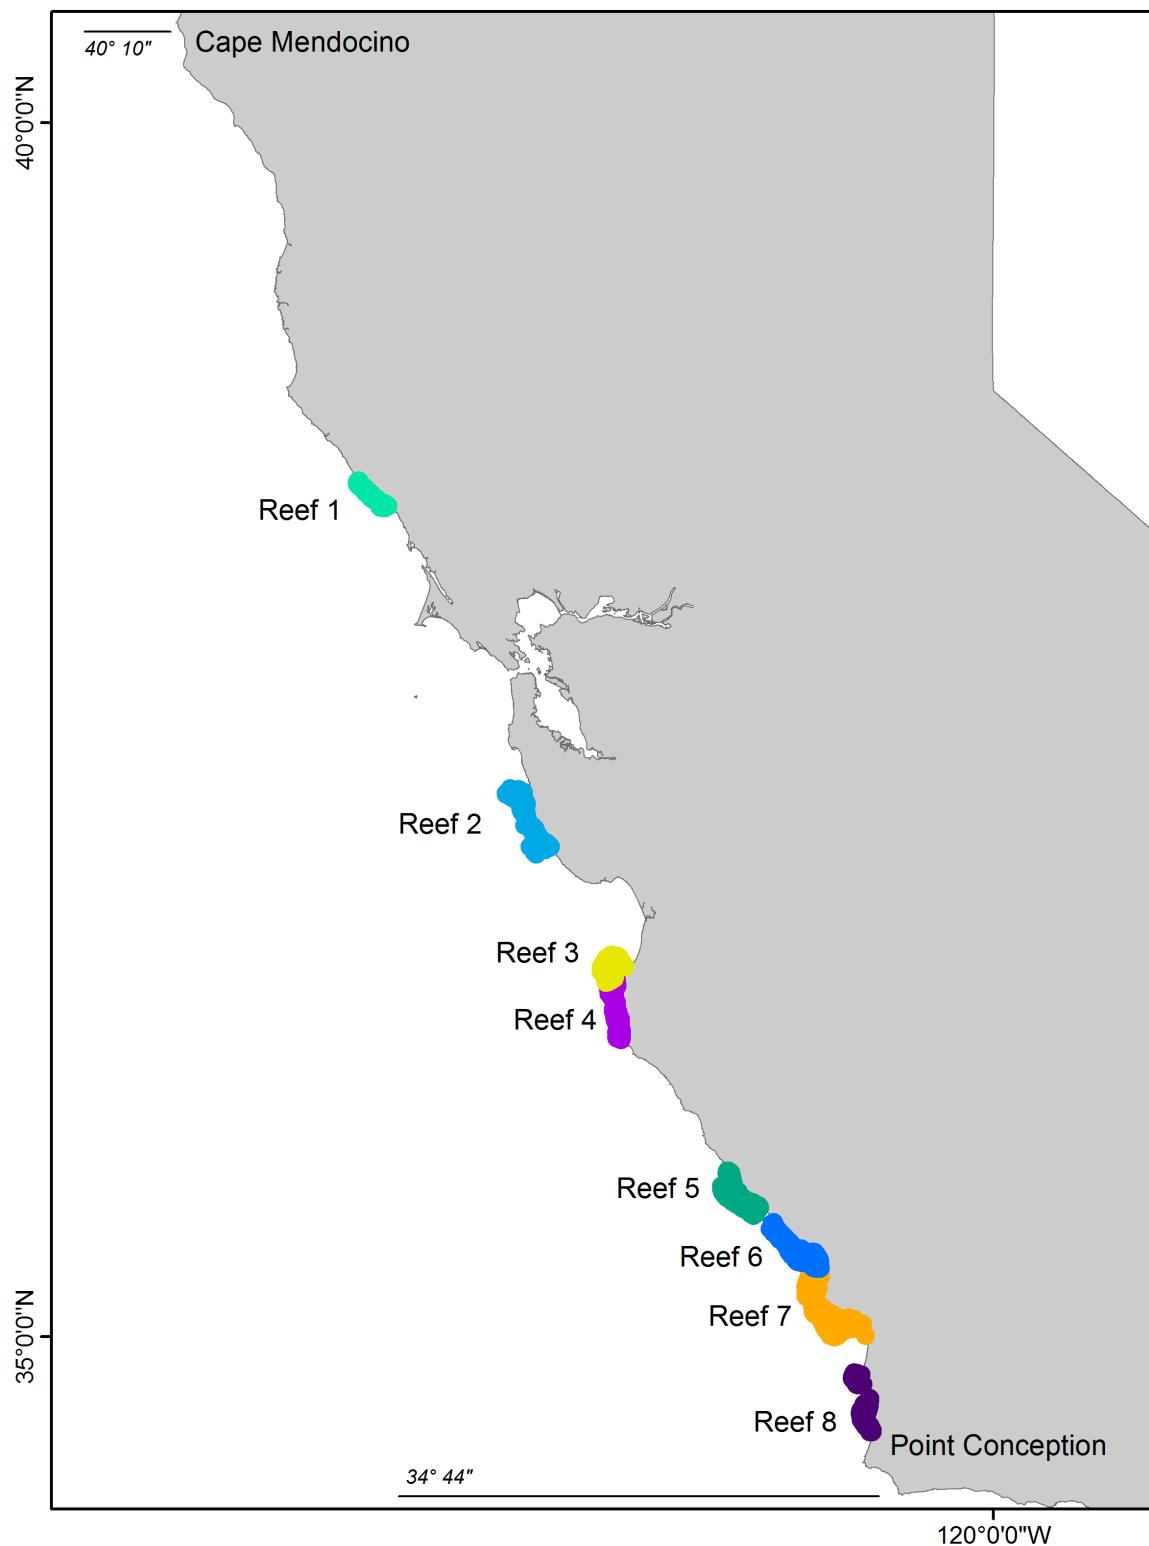

Figure 19: Map of the reefs used in the Deb Wilson-Vandenberg CPFV onboard observer survey index of abundance. [fig:DebWV_sites](#)

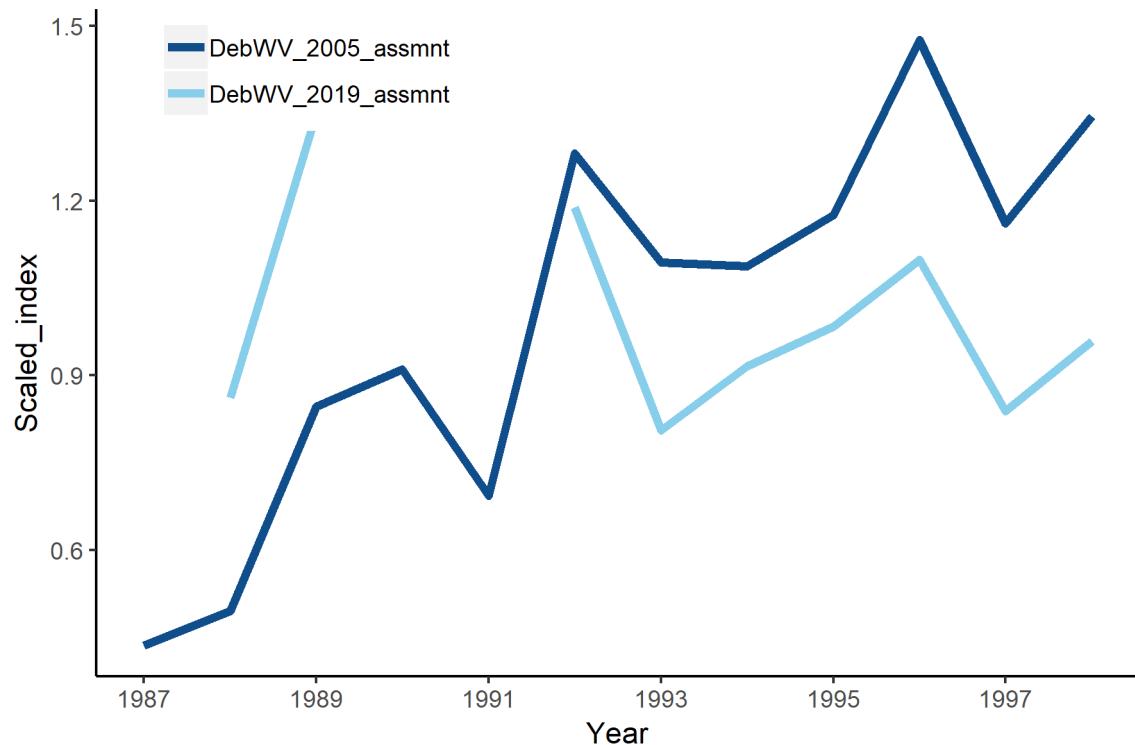

Figure 20: Comparison of the index developed for the Deb Wilson-Vandenberg CPFV onboard observer survey from the 2005 assessment and for the 2019 assessment. [Fig:DebWV_index_compare](#)

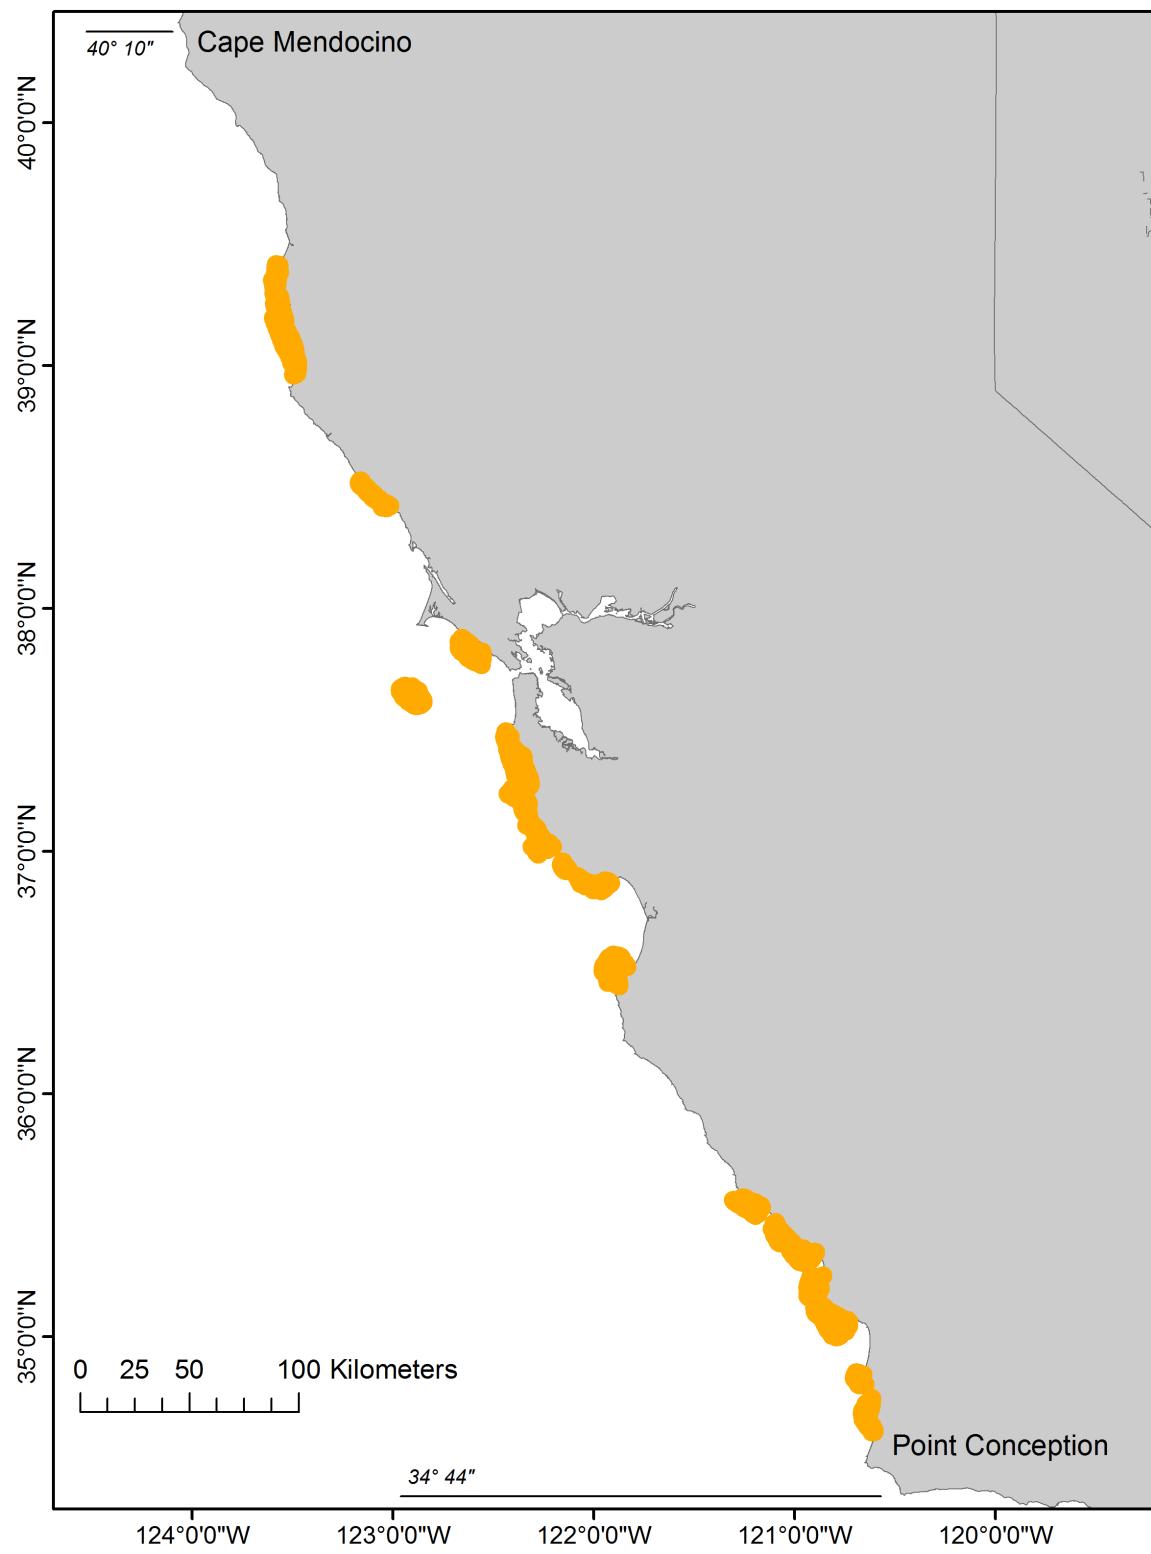

Figure 21: Map of the reefs selected for the final index for the onboard observer surveys (CDFW and Cal Poly) north of Point Conception

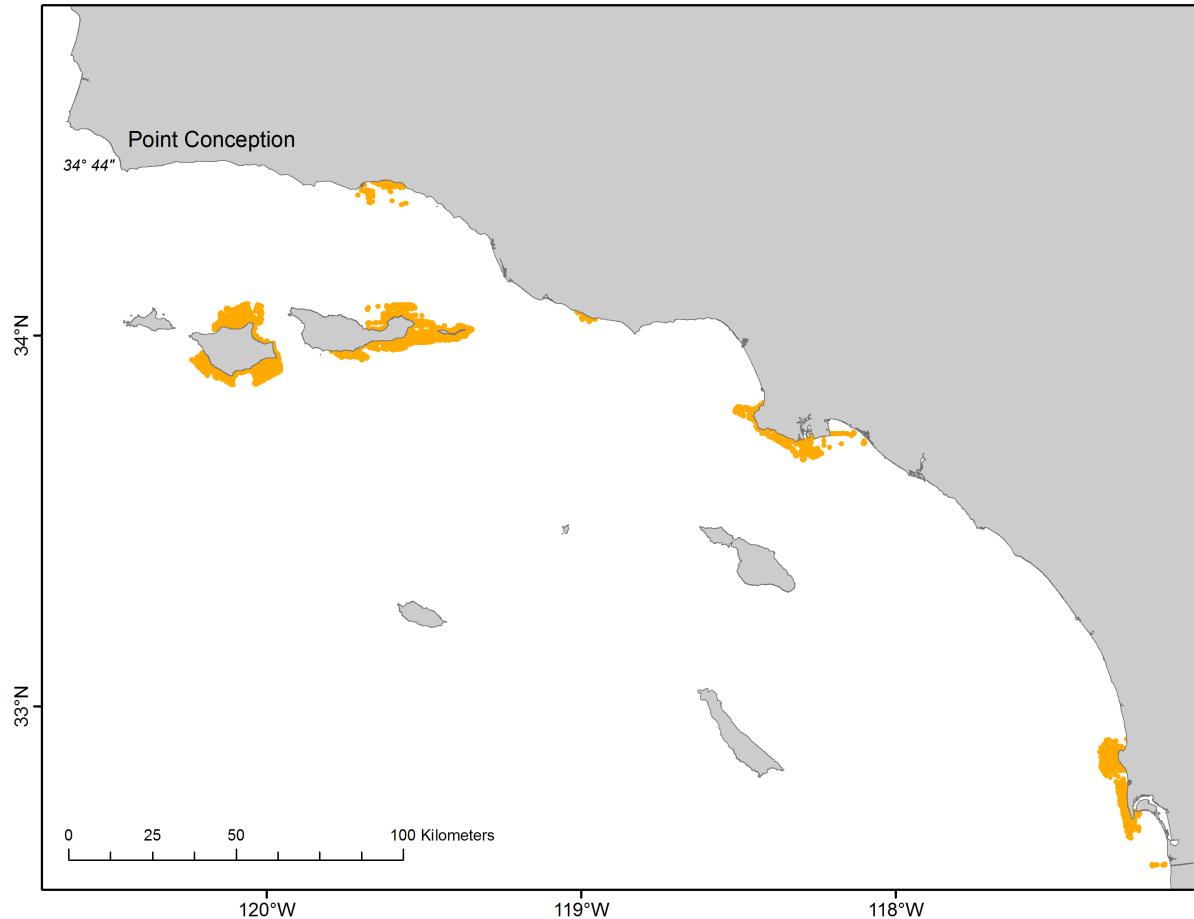

Figure 22: Map of the reefs selected for the final index for the CDFW onboard observer survey south of Point Conception | [fig:Unboard_observer_south_sites](#)

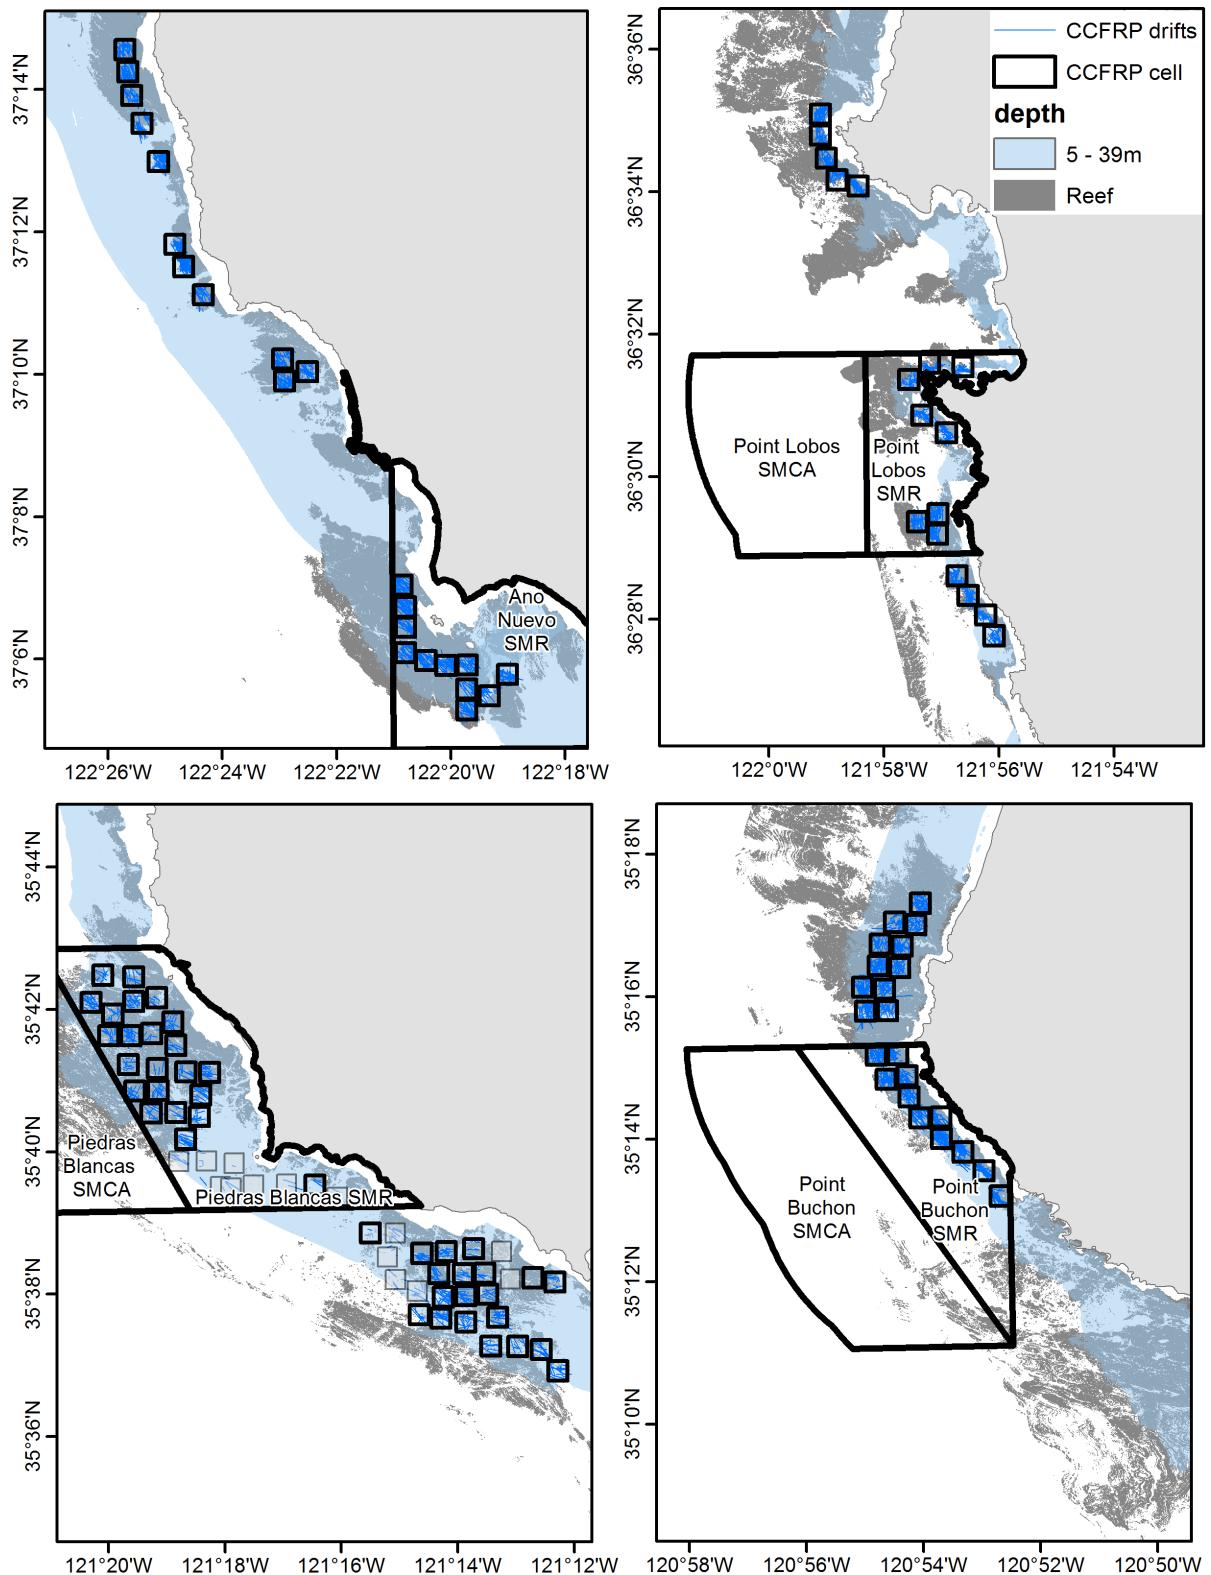

Figure 23: Map of the four MPAs sampled consistently through time for the CCFRP fishery-independent survey. [fig:CCFRP_sites](#)

MLEs vs. Posterior Medians

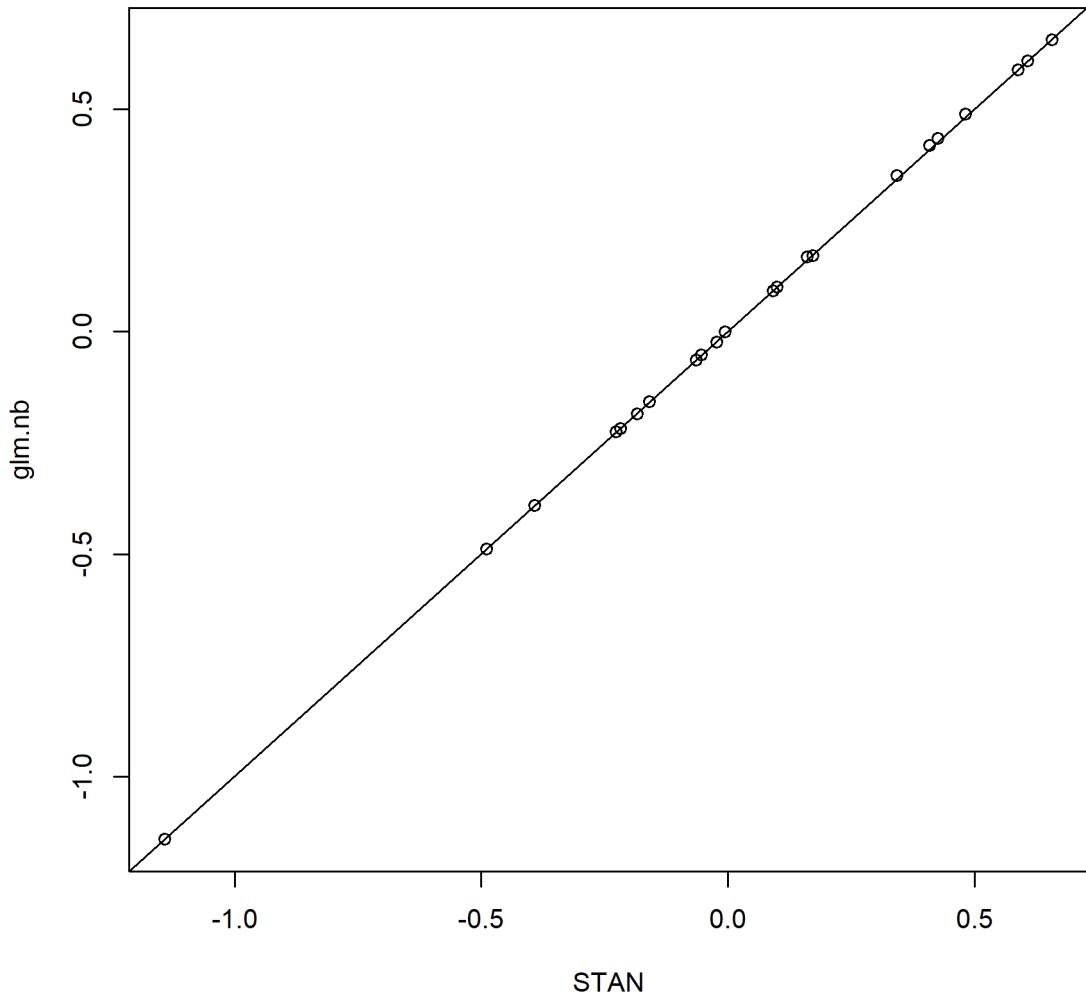

Figure 24: Comparison of negative binomial predictions (CPUE) to observed means in each stratum (year) for the CCFRP index. The 1:1 plot is for reference.

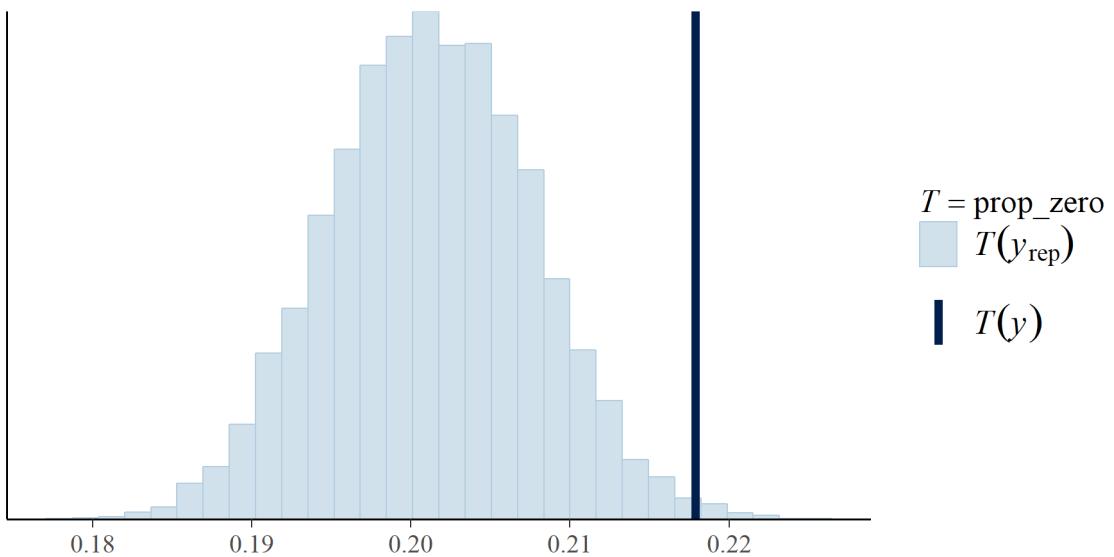

Figure 25: Posterior predictive distribution of the proportion of zero observations in replicate data sets generated by the negative binomial model for the CCFRP index. [fig:Fleet9_prop_zero_STAN](#)

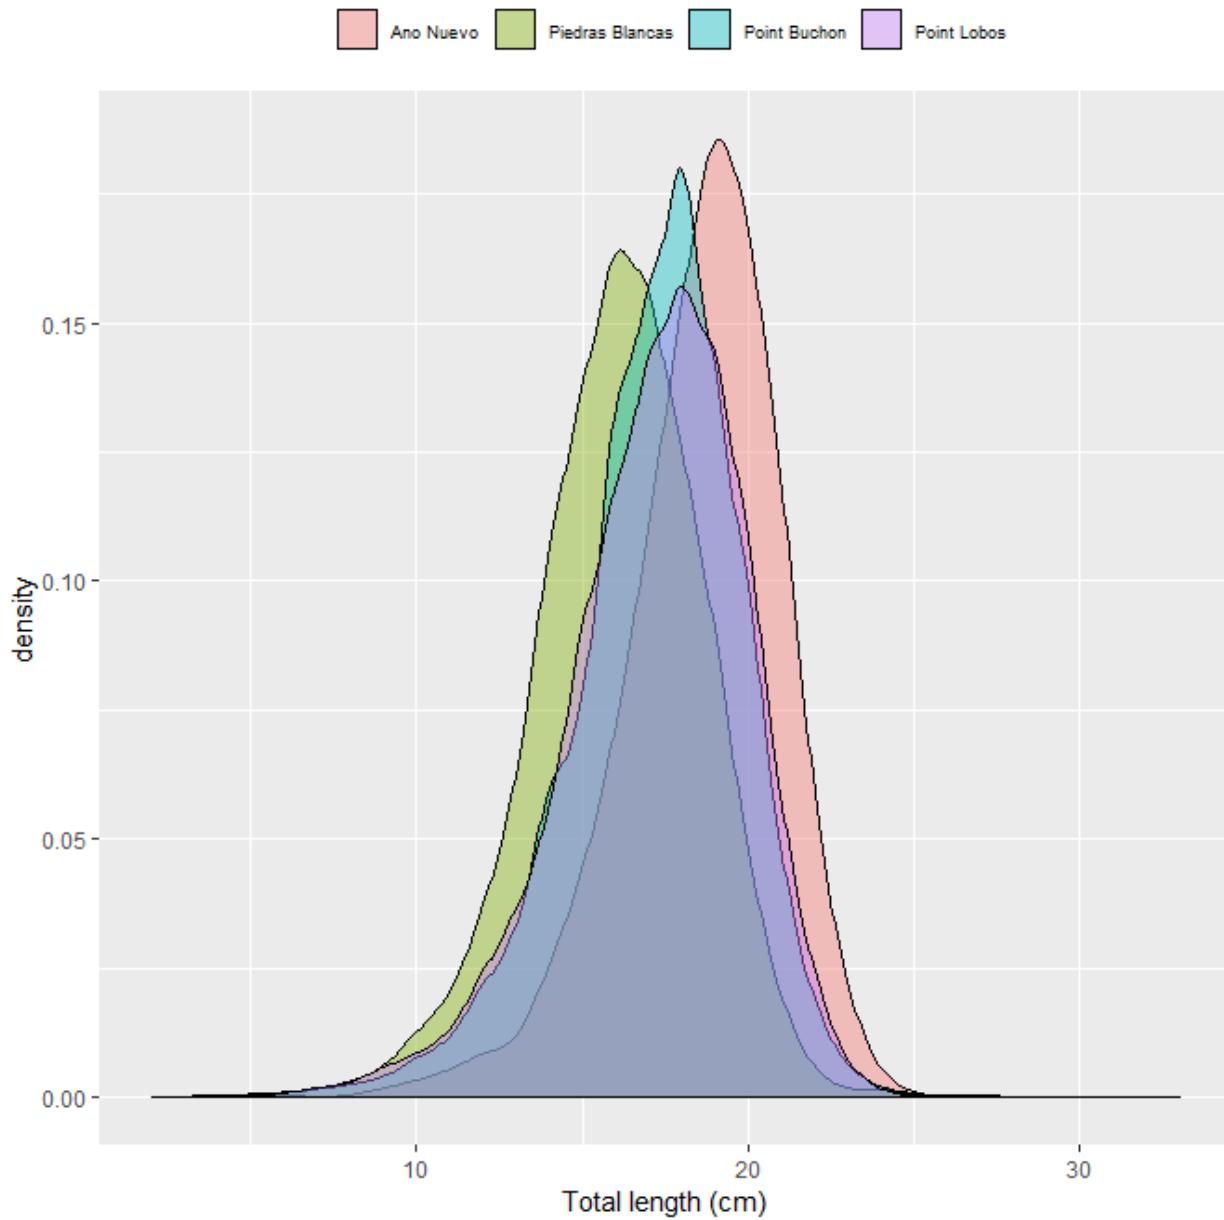

Figure 26: Length distributions of GBYR for the four MPAs sampled by the CCFRP survey used in this assessment. | [CCFRP_lengths_by_site](#)

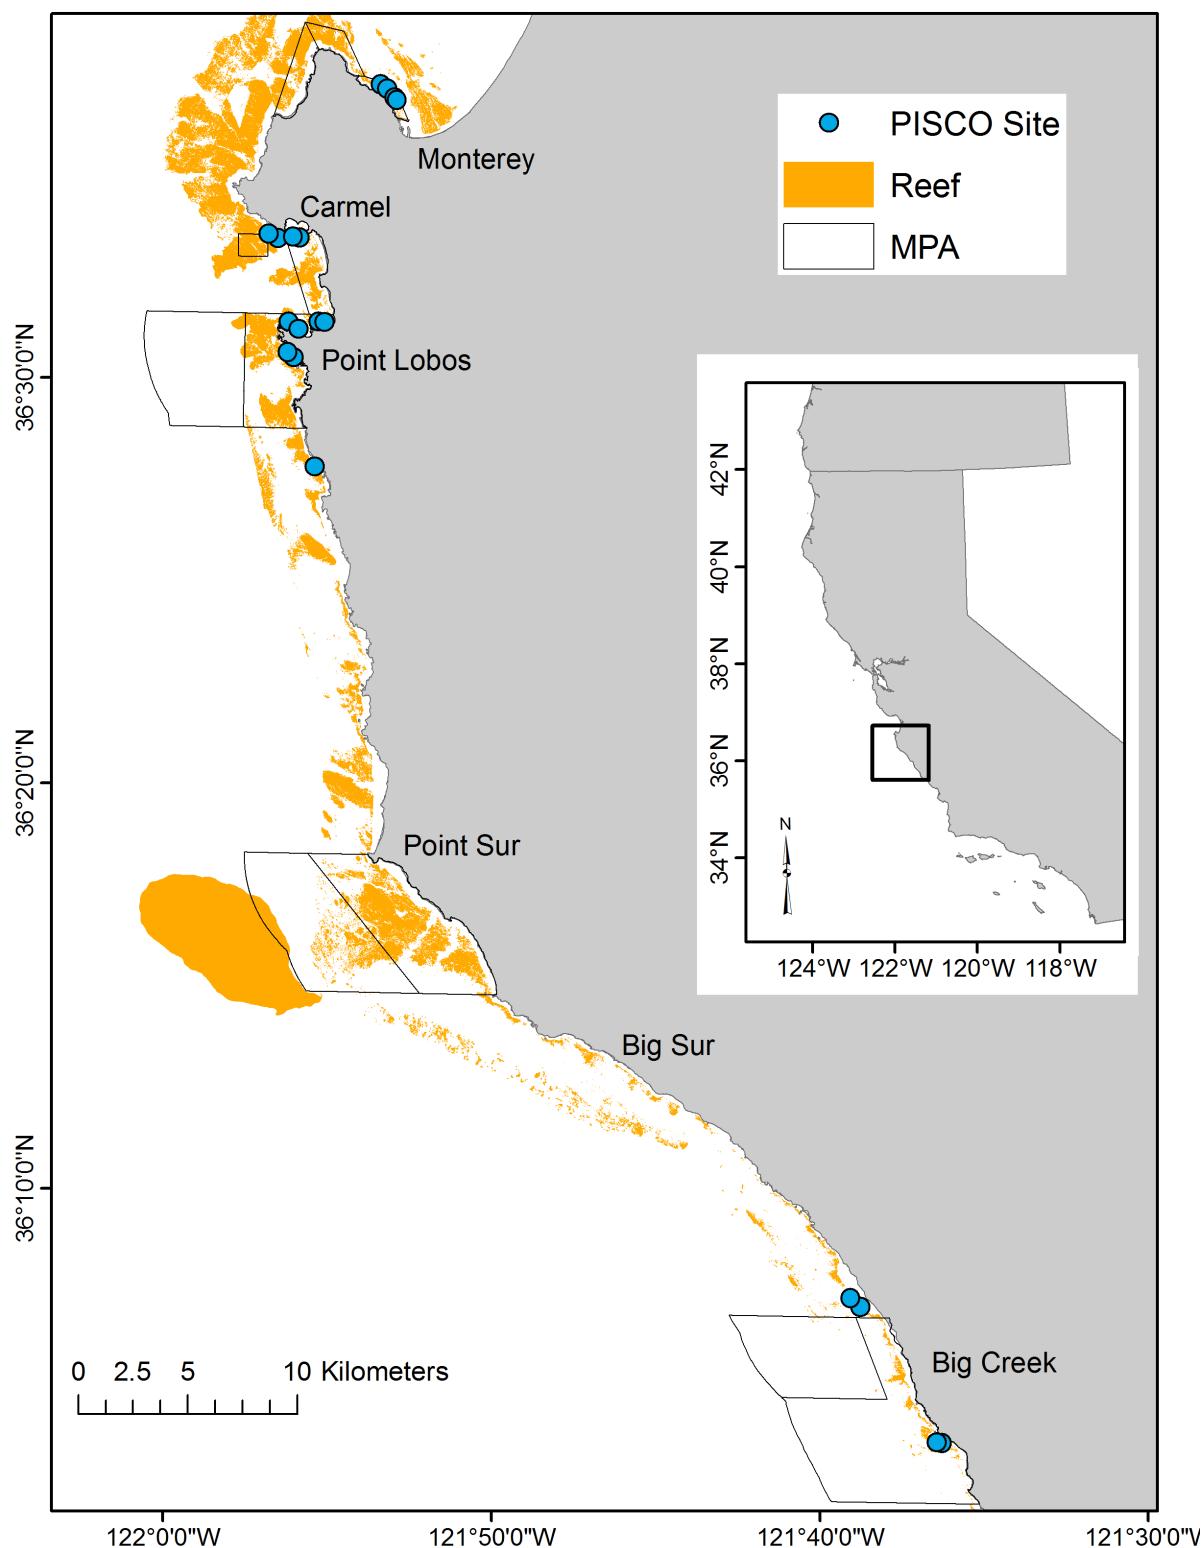

Figure 27: Map of the sites sampled consistently through time for the PISCO kelp forest fish survey. | [fig:PISCO_sites](#)

MLEs vs. Posterior Medians

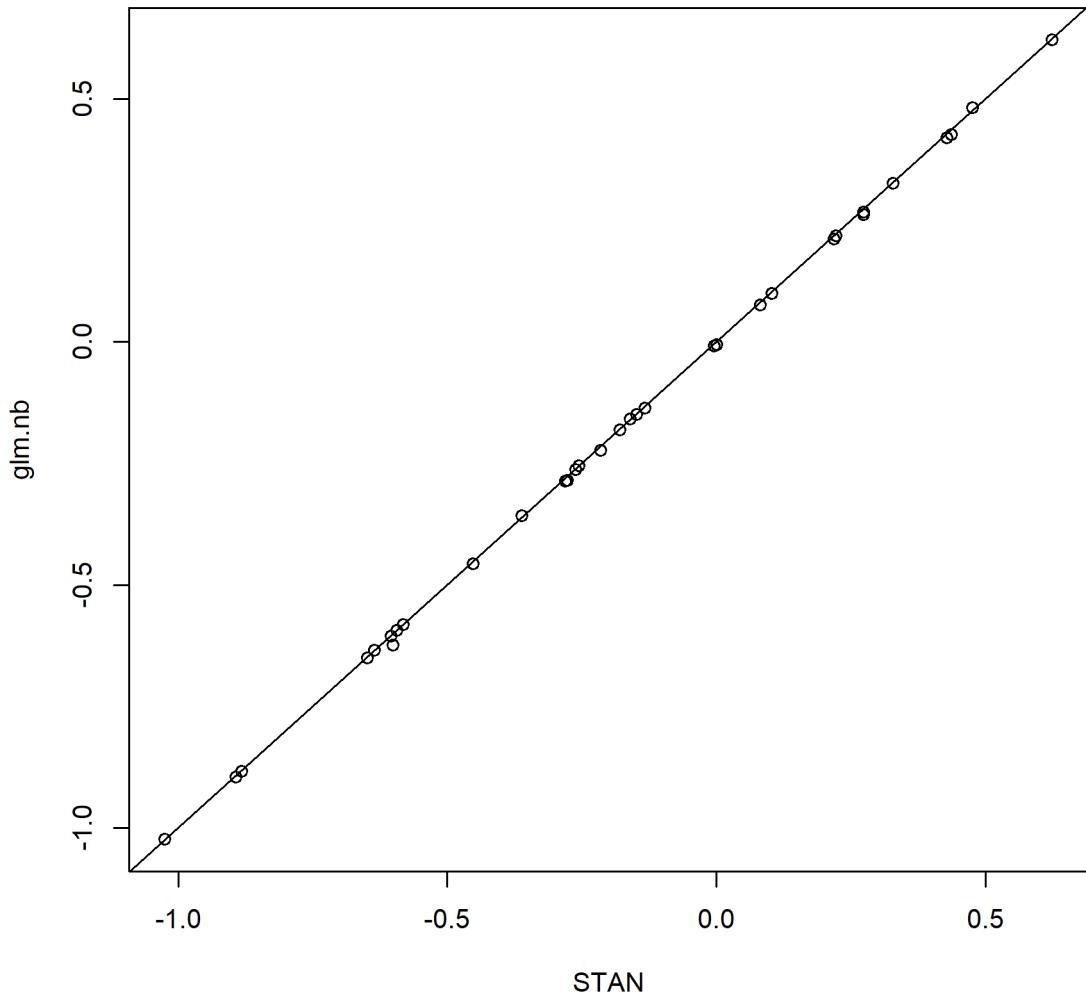

Figure 28: Comparison of negative binomial predictions (CPUE) to observed means in each stratum (year) for the PISCO kelp forest fish survey index. The 1:1 plot is for reference. [fig:Fleet8_MLE](#)

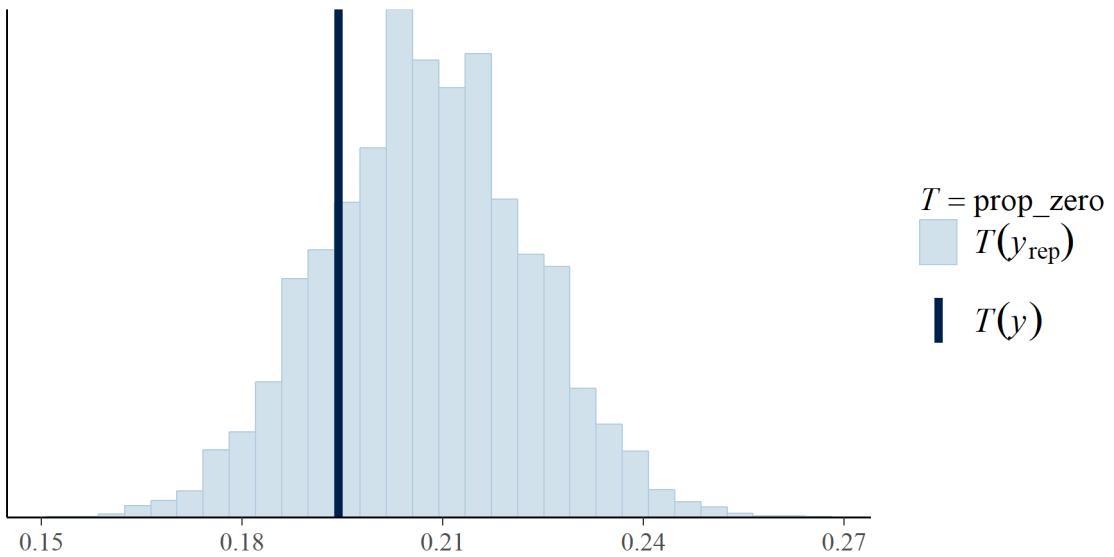

Figure 29: Posterior predictive distribution of the proportion of zero observations in replicate data sets generated by the negative binomial model for the PISCO kelp forest fish survey. [fig:Fleet8_pr](#)

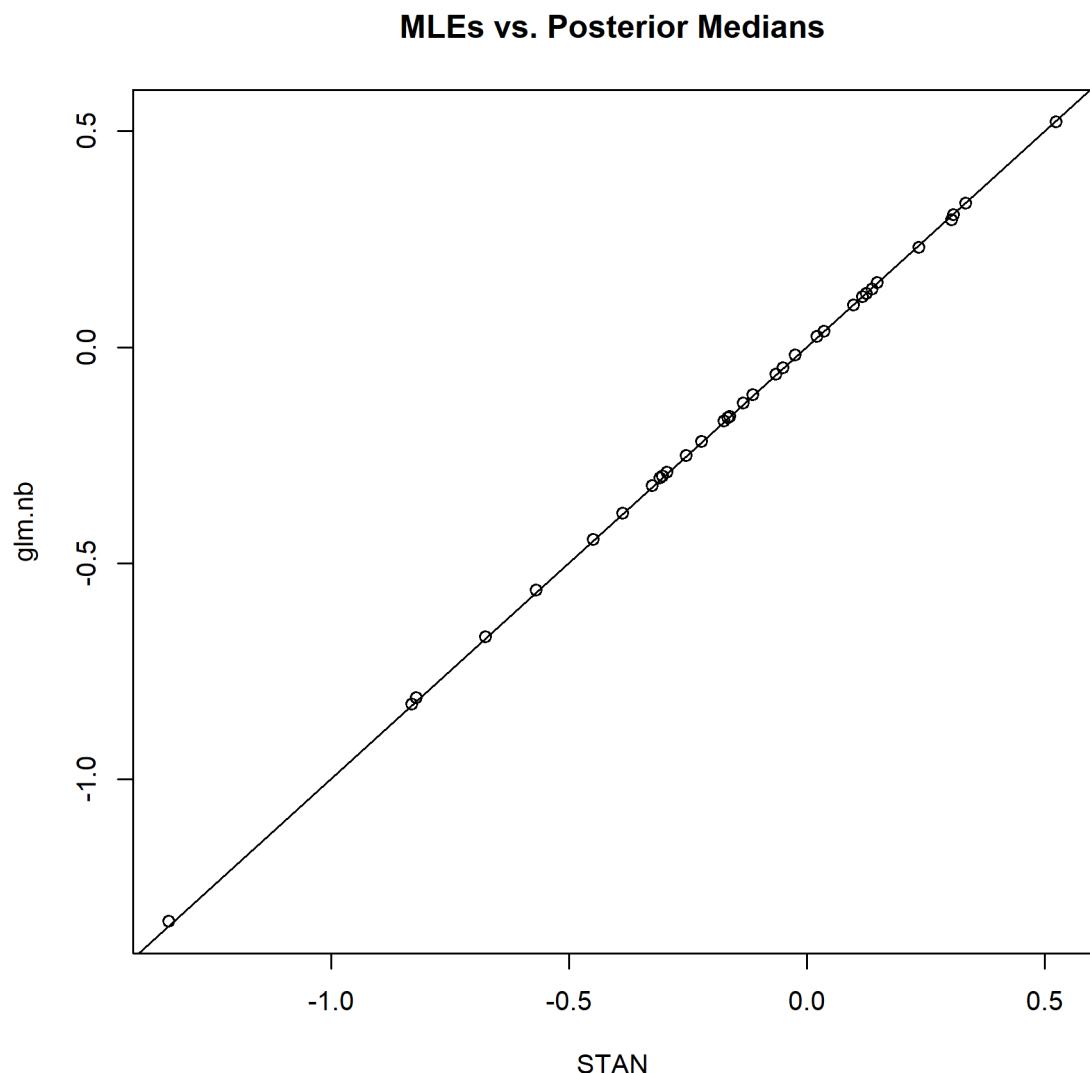

Figure 30: Comparison of negative binomial predictions (CPUE) to observed means in each stratum (year) for the PISCO kelp forest fish survey index for fish 15 cm and larger. The 1:1 plot is for reference. fig:Fleet8large_MLE_stan

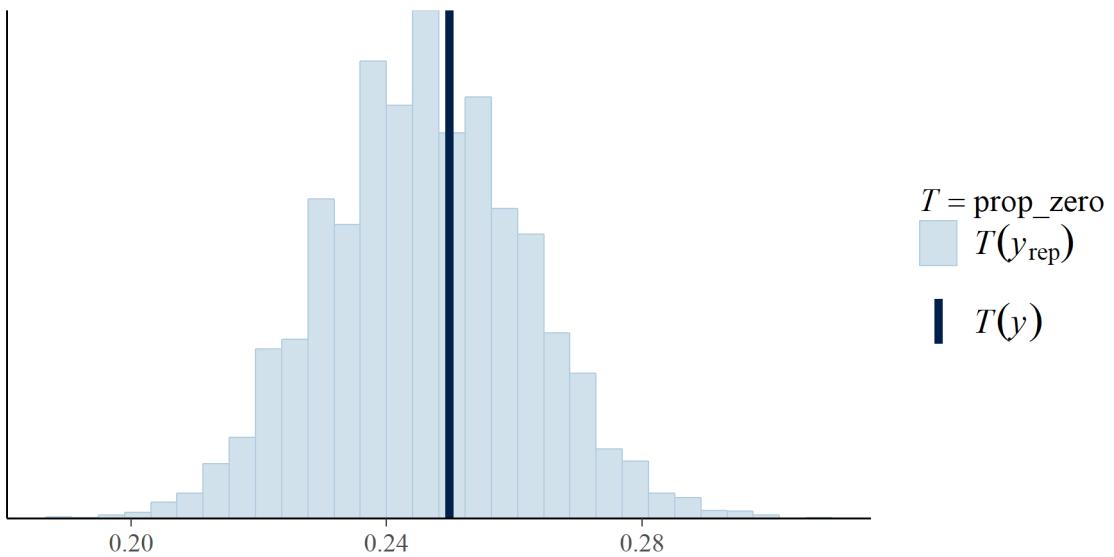

Figure 31: Posterior predictive distribution of the proportion of zero observations in replicate data sets generated by the negative binomial model for the PISCO kelp forest fish survey for fish 15 cm and larger. [fig:Fleet8large_prop_zero_STAN](#)

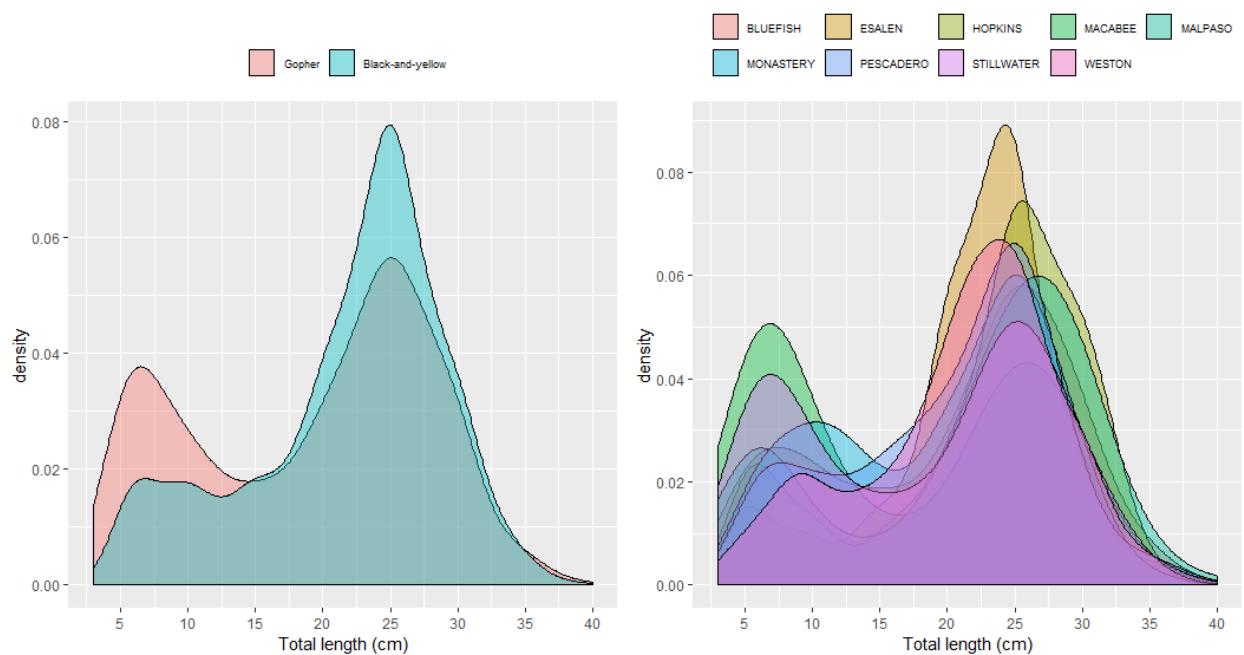

Figure 32: Plots of the length distributions from the PISCO kelp forest fish survey by species (left) and for combined species by site (right) for sites included in the final index of abundance. [fig:PISCO_lengths](#)

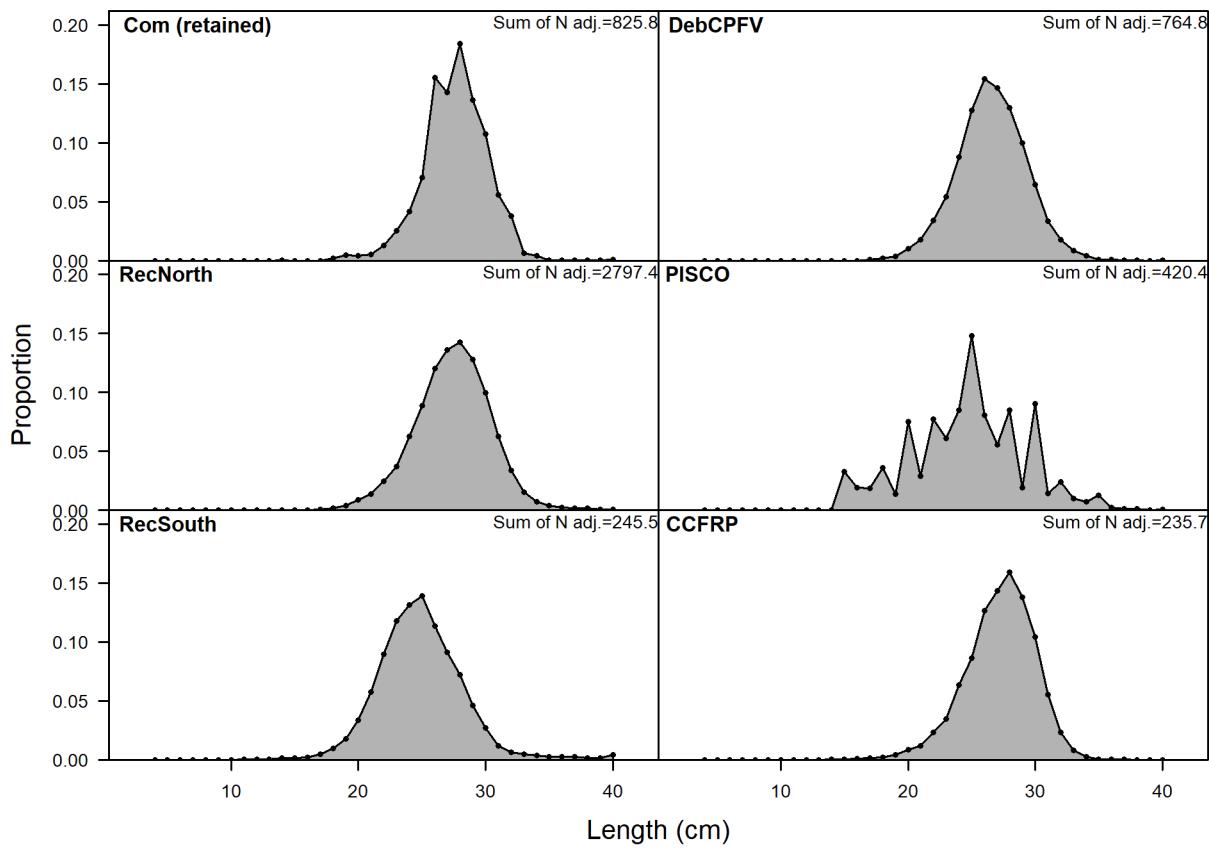

Figure 33: Length comp data, aggregated across time by fleet. Labels ‘retained’ and ‘discard’ indicate discarded or retained sampled for each fleet. Panels without this designation represent the whole catch. | [fig:comp_lendat_aggregated_across_time](#)

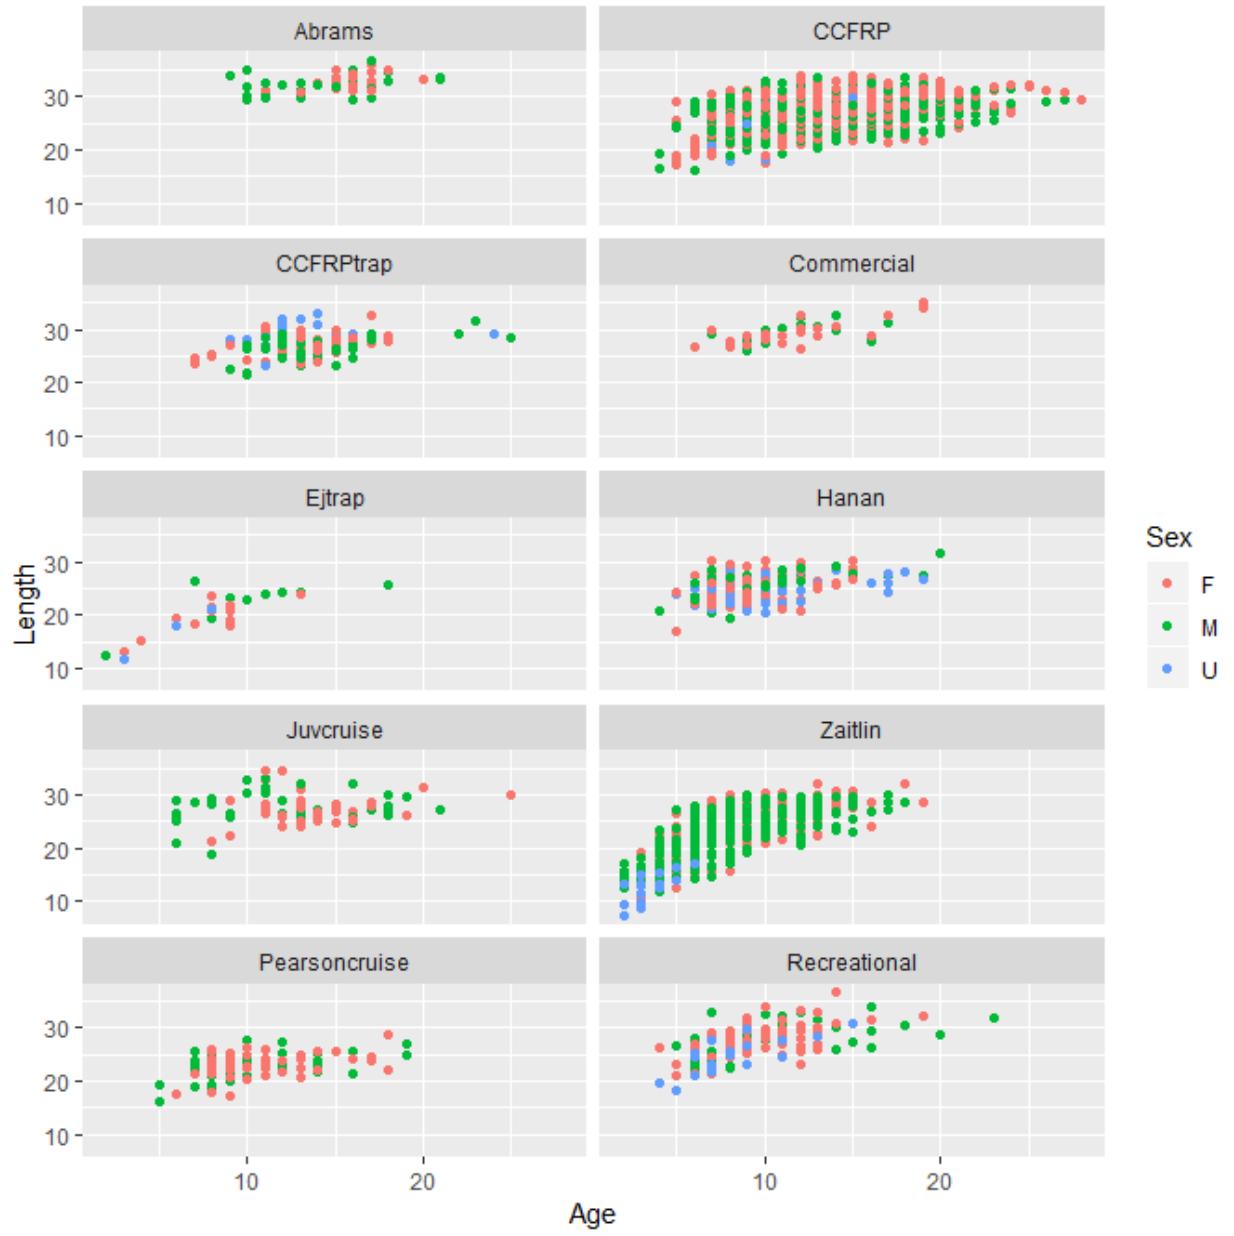

Figure 34: Available length-at-age data for gopher and black-and-yellow rockfish by sex and data source. The Zaitlin study is all black-and-yellow rockfish. The remaining plots represent gopher rockfish

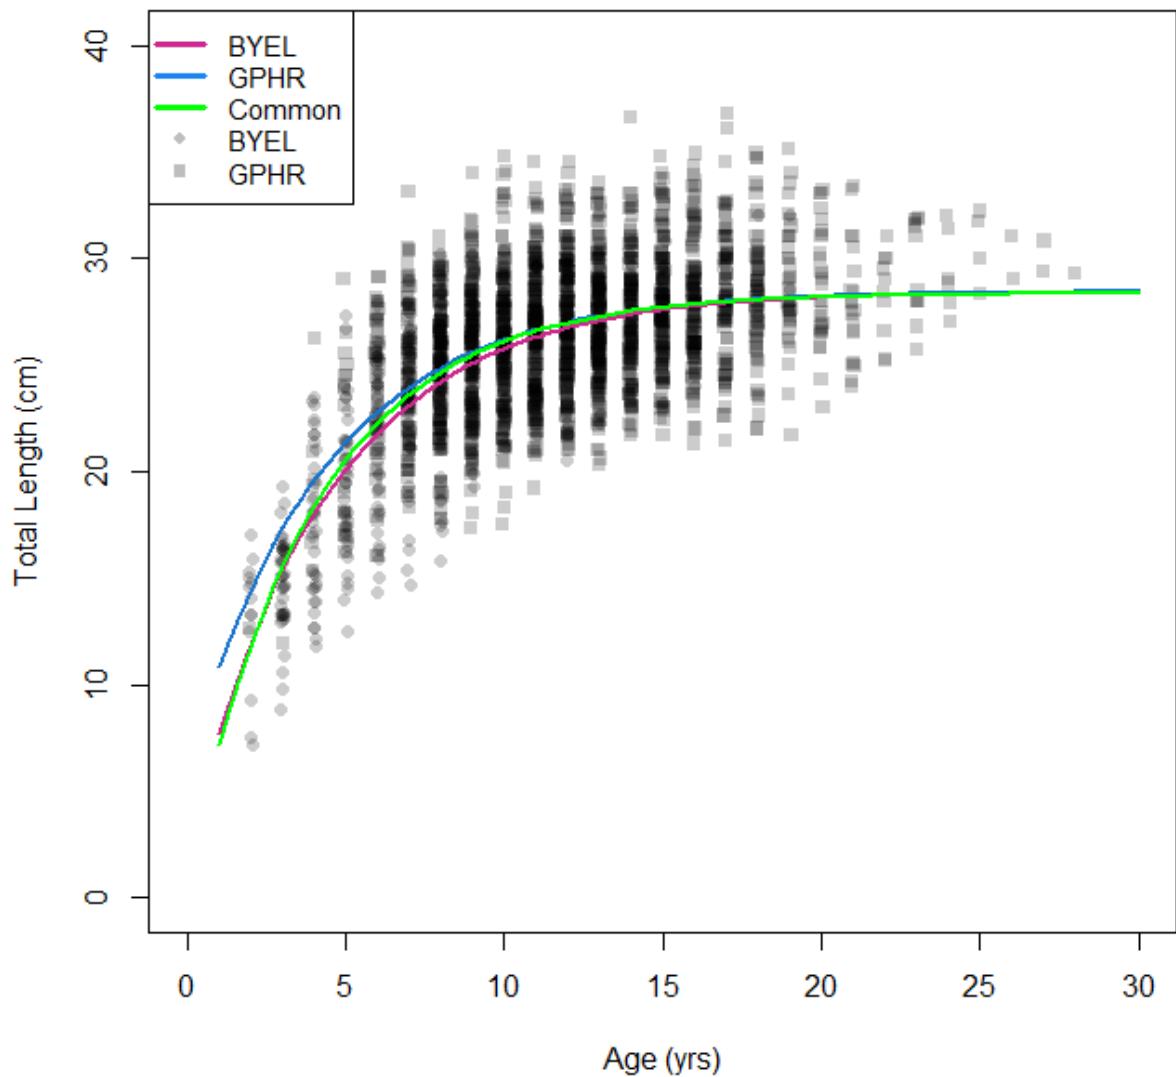

Figure 35: External estimates of growth for gopher and black-and-yellow rockfish from fits to von Bertalanffy growth models. | [Growth_by_species](#)

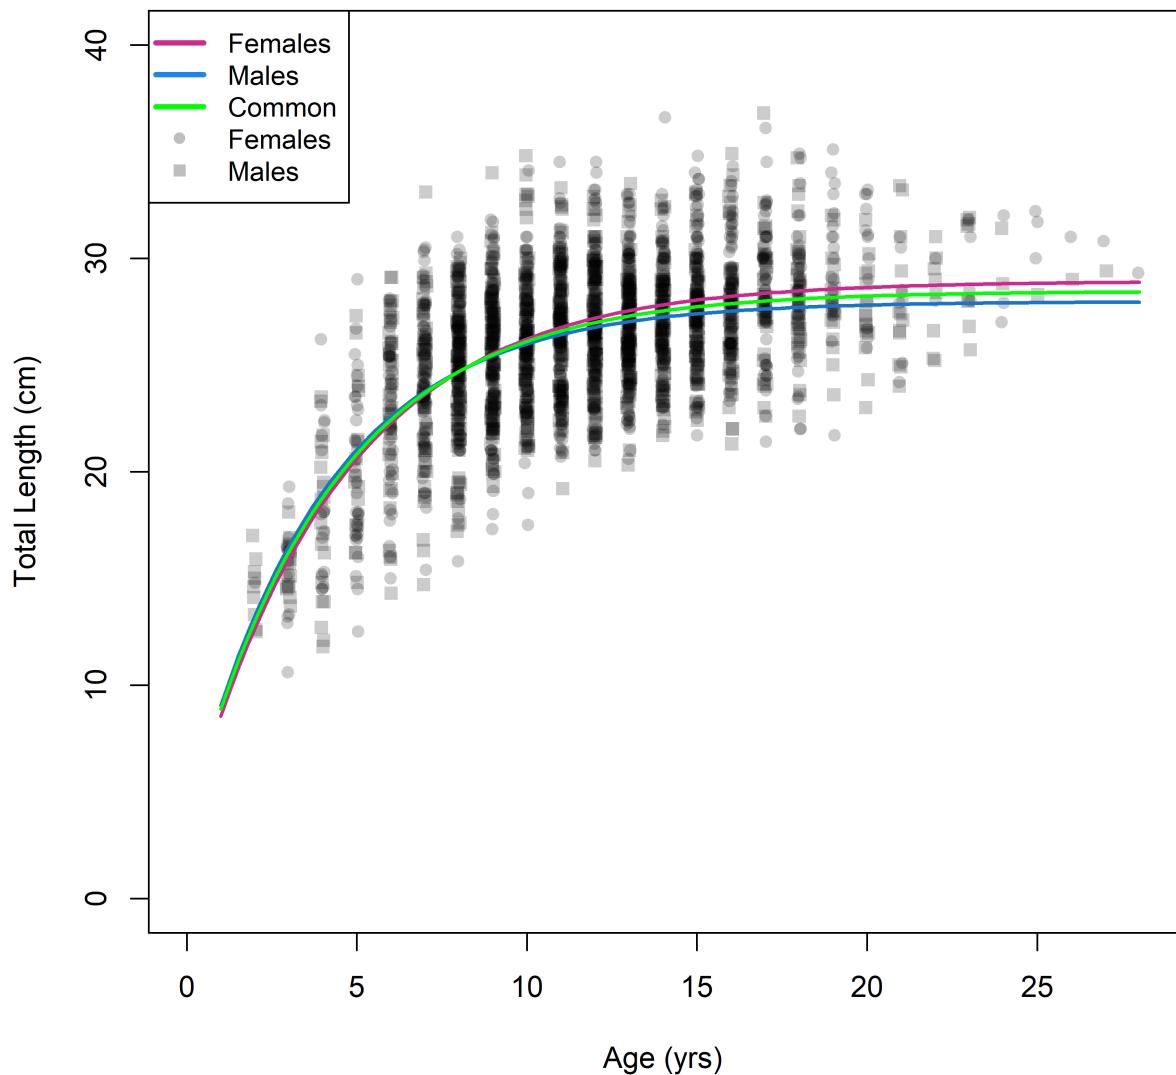

Figure 36: External estimates of growth for GBYR combined by sex from fits to von Bertalanffy growth models. | [Growth_by_sex](#)

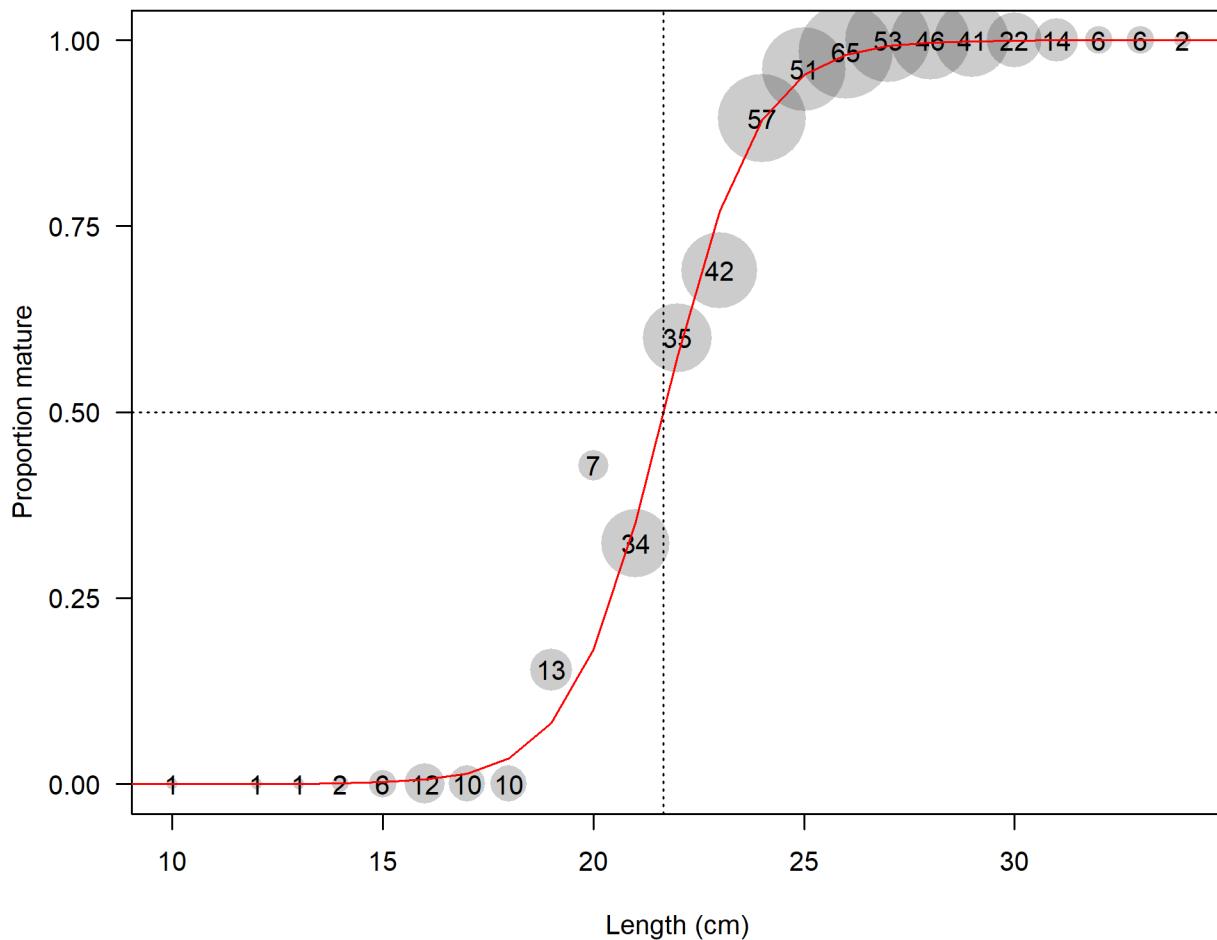

Figure 37: Maturity ogive for females estimated from black-and-yellow rockfish from Zaitlin (1986) and gopher rockfish from Meyers-Cherry (2014). Sample sizes at a given length are shown in the circles. [fig:GBY_maturity_ogive](#)

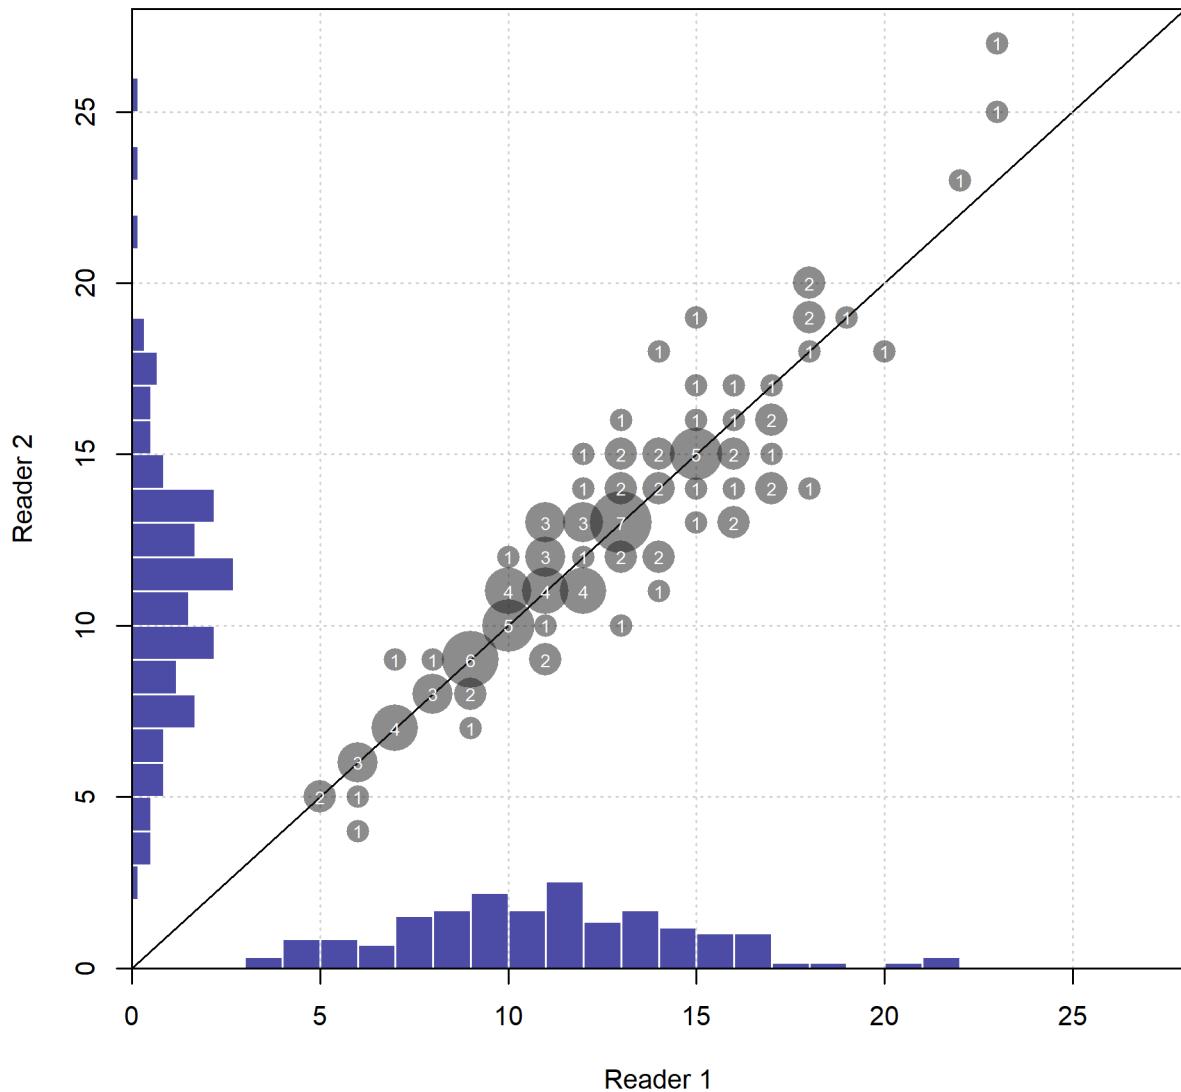

Figure 38: Aging precision between initial and blind double reads for GBYR. Numbers in the bubbles are the sample sizes of otoliths cross-read. [fig:GBY_age_error](#)

Reads(dot), Sd(blue), expected_read(red solid line),
and 95% CI for expected_read(red dotted line)

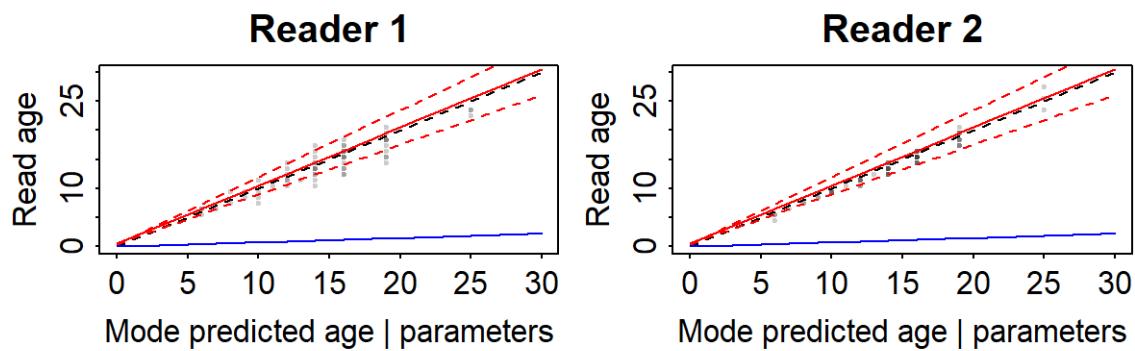

Figure 39: True versus predicted age for two current age readers at the NWFSC from the ageing error software with unbiased reads and curvilinear standard deviation for both readers.
fig:GBY_age_error2

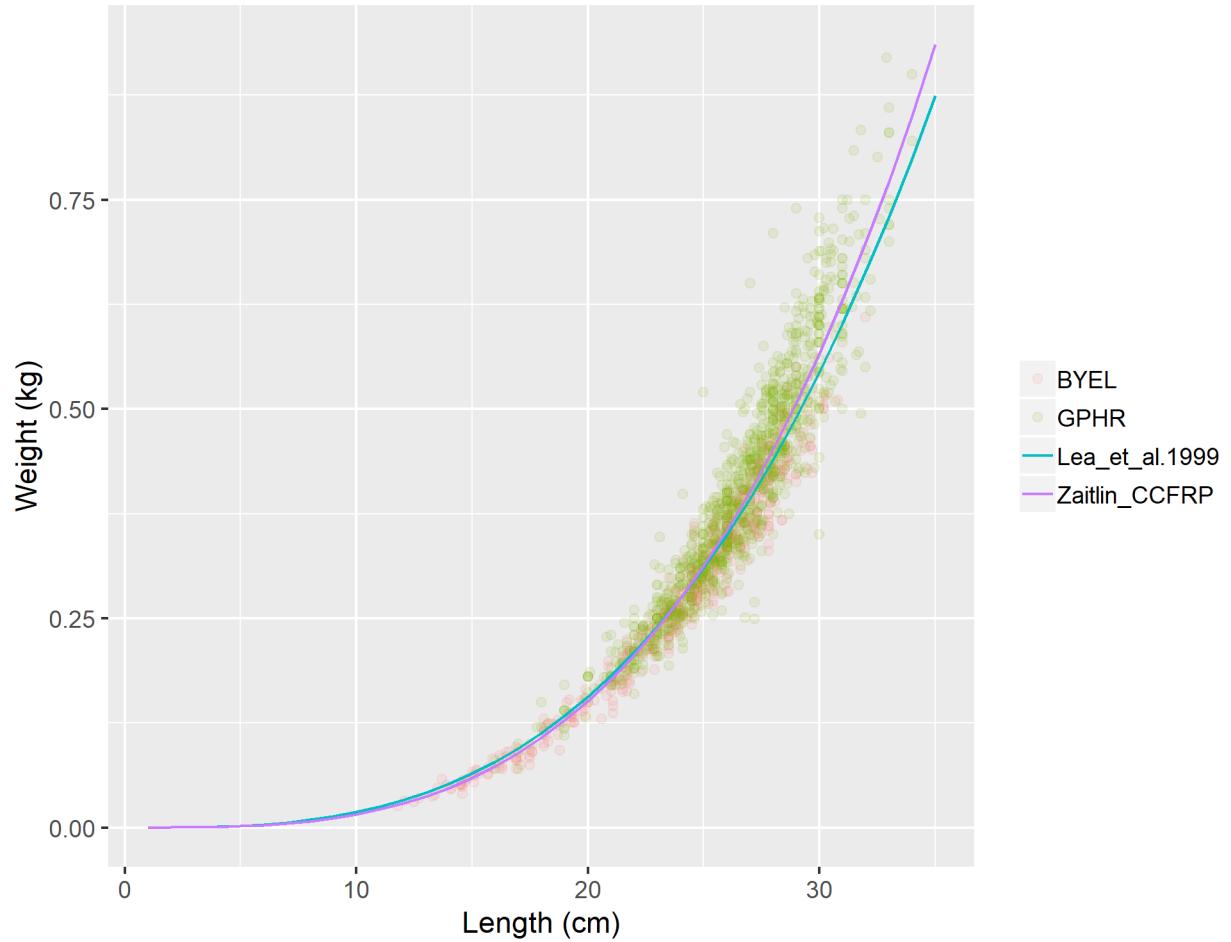

Figure 40: Comparison of the gopher rockfish weight-length curves from Lee et al. (1999) and the estimated from black-and-yellow rockfishes from Zaitlin (1986), and gopher rockfishes from Loury (2011) and Meyers-Cherry(2014). The estimated curve from the current data is used in this assessment. [fig:GBY_weight_length](#)

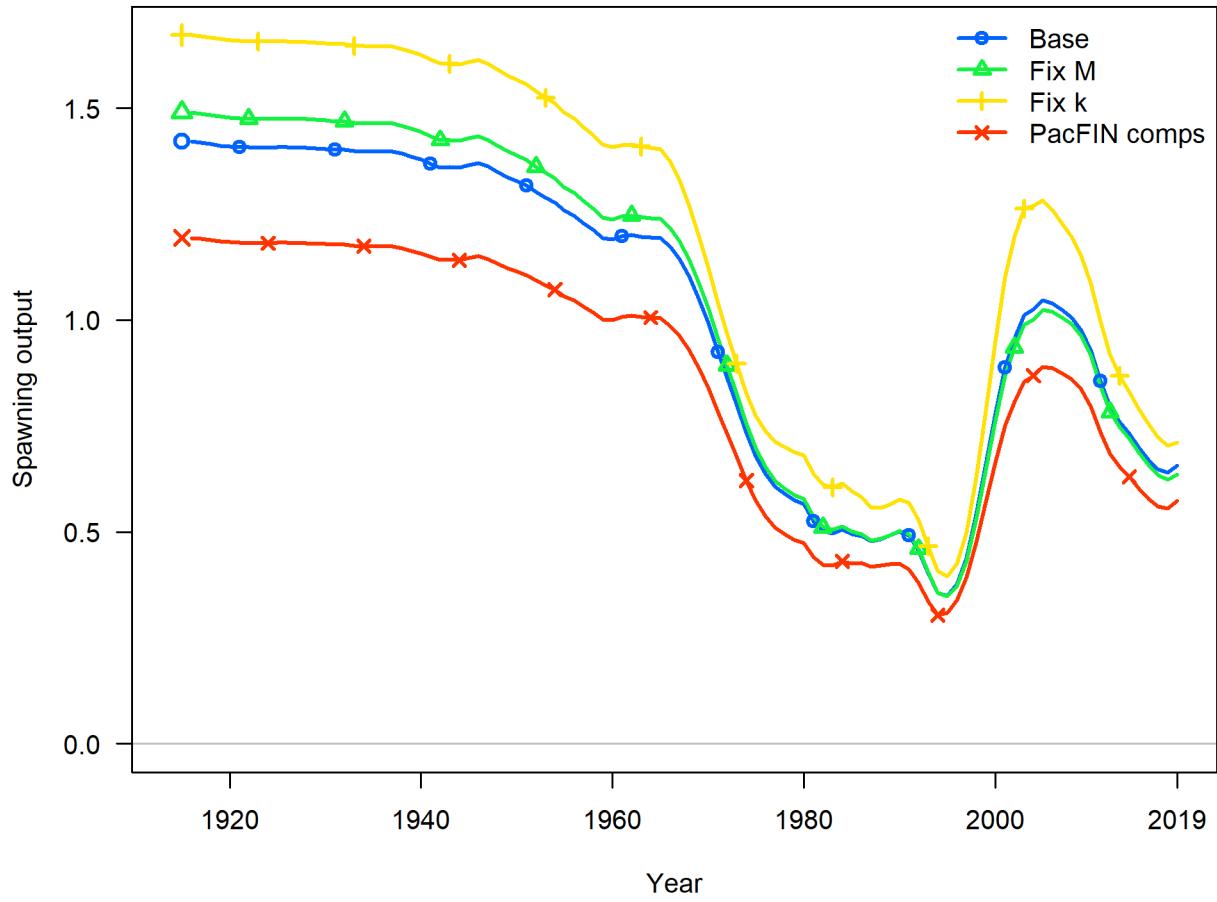

Figure 41: Sensitivity of the spawning biomass to fixing natural mortality to the prior, fixing the von Bertalanffy k parameter to the external estimate, or using commercial PacFIN length composition data instead of CALCOM, as compared to the pre-STAR base model. [fig:sensitivity1_spaw](#)

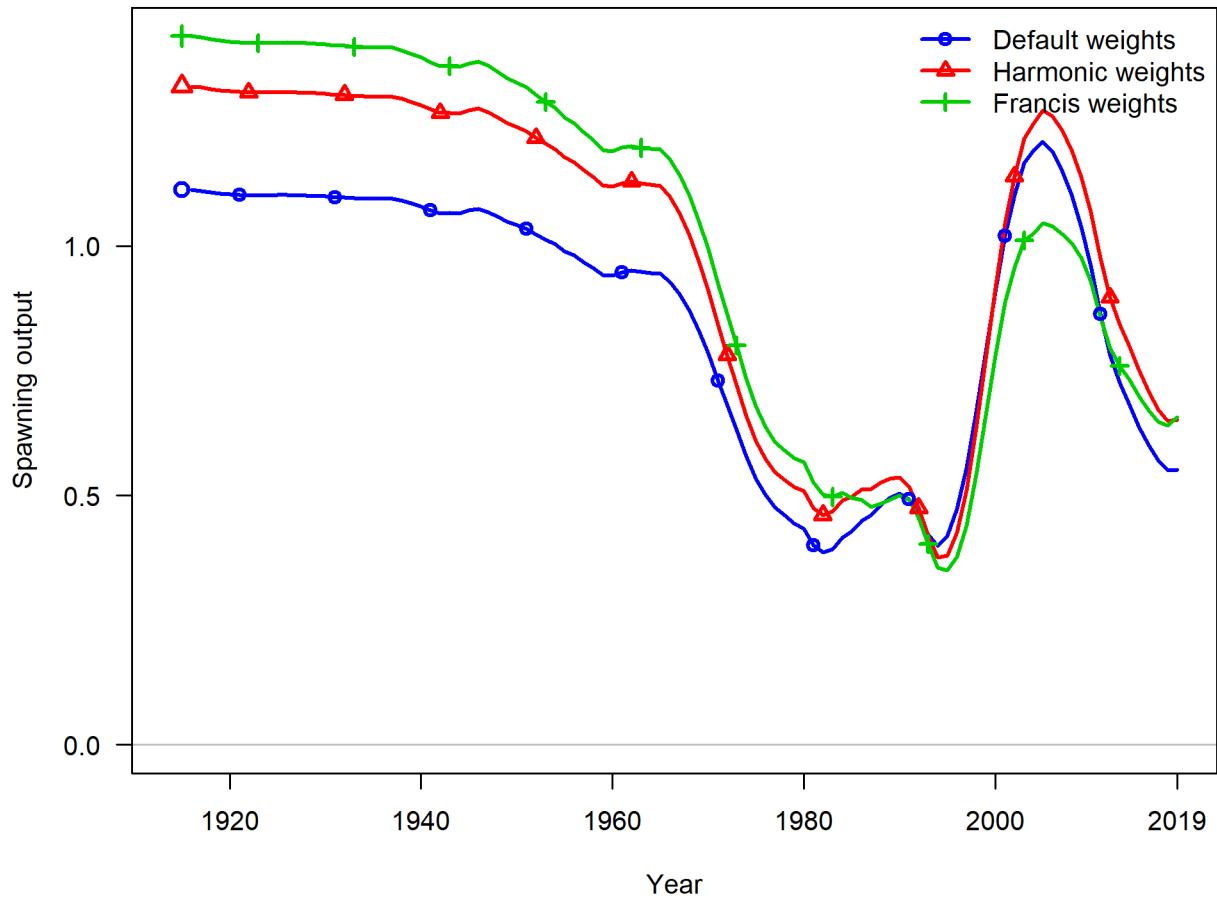

Figure 42: Sensitivity of the spawning biomass to either the default weight of composition data, the harmonic mean, or Francis weights. [fig:sensitivity2_spawnbio](#)

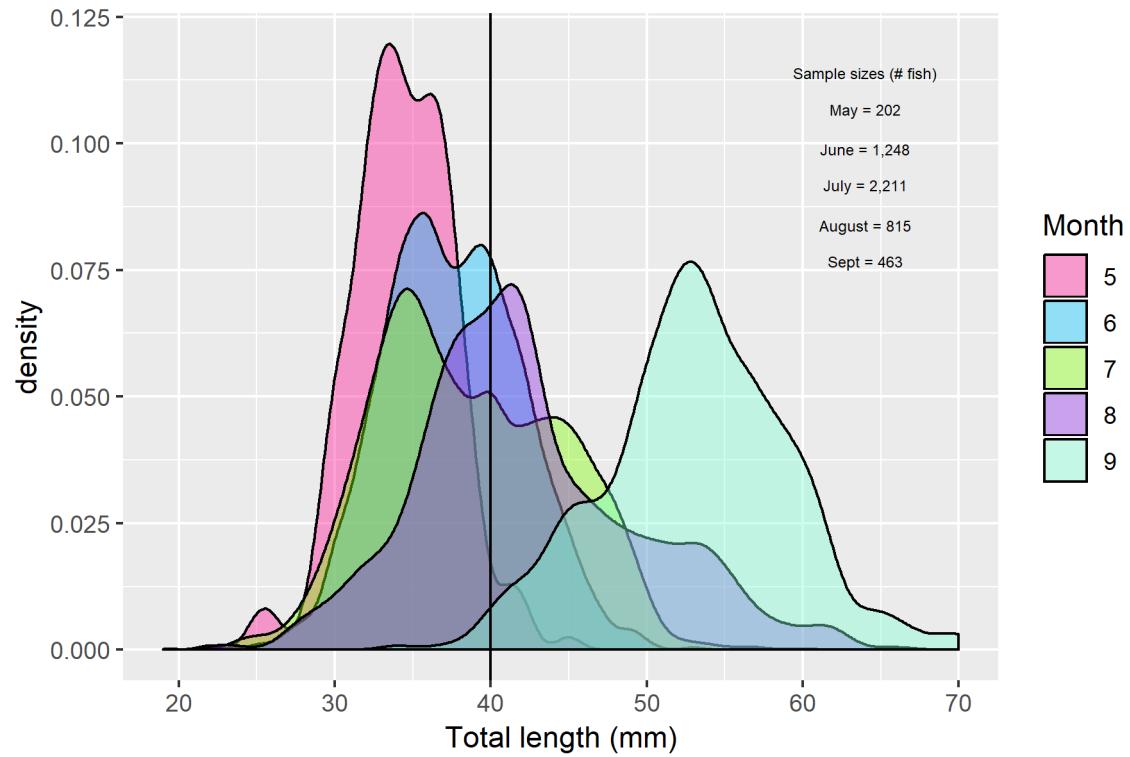

Figure 43: Length distribution by month for GBYR captured using a sampling tool called a Standard Monitoring Unit for the Recruitment of Fishes (SMURFs) from the UCSC-PISCO kelp forest fish survey, specifically as part of Diana Baetscher's dissertation work (Baetscher 2019). [fig:SMURF_lengths](#)

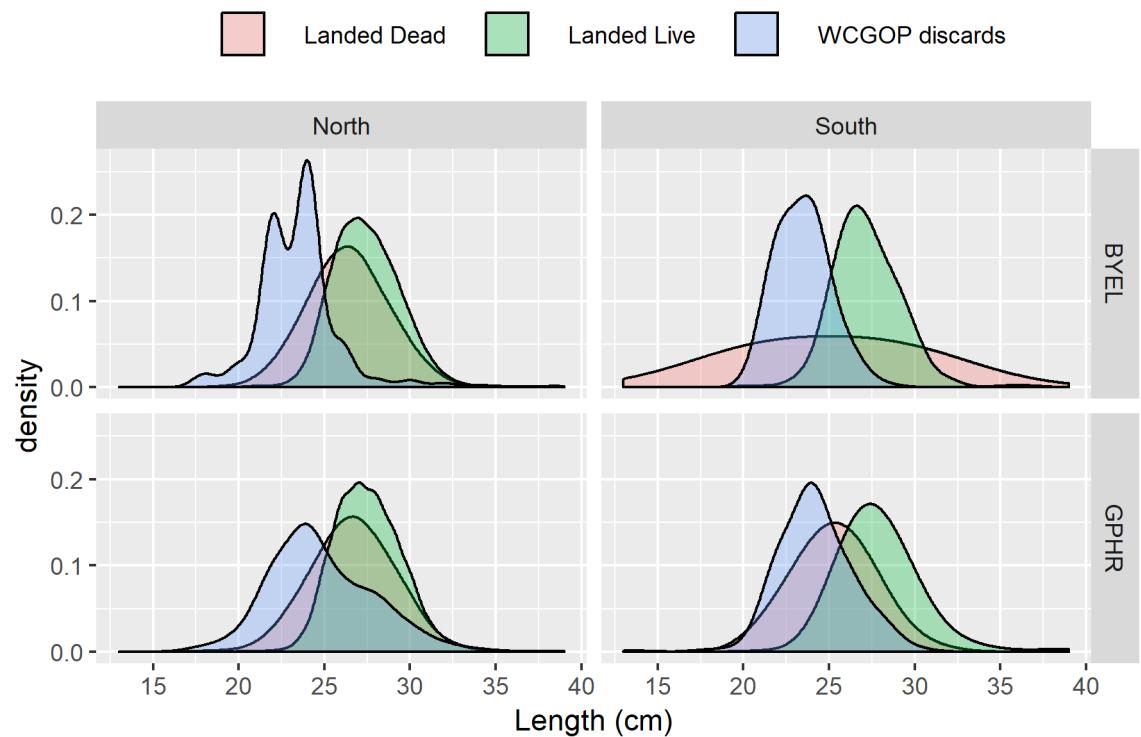

Figure 44: Length distributions of gopher and black-and-yellow rockfish for the commercial fleet and WCGOP discards north and south of Point Conception. The commercial landings were also separated between fish landed live and fish landed dead for this figure. ^{fig:Comm_lengths_justi}

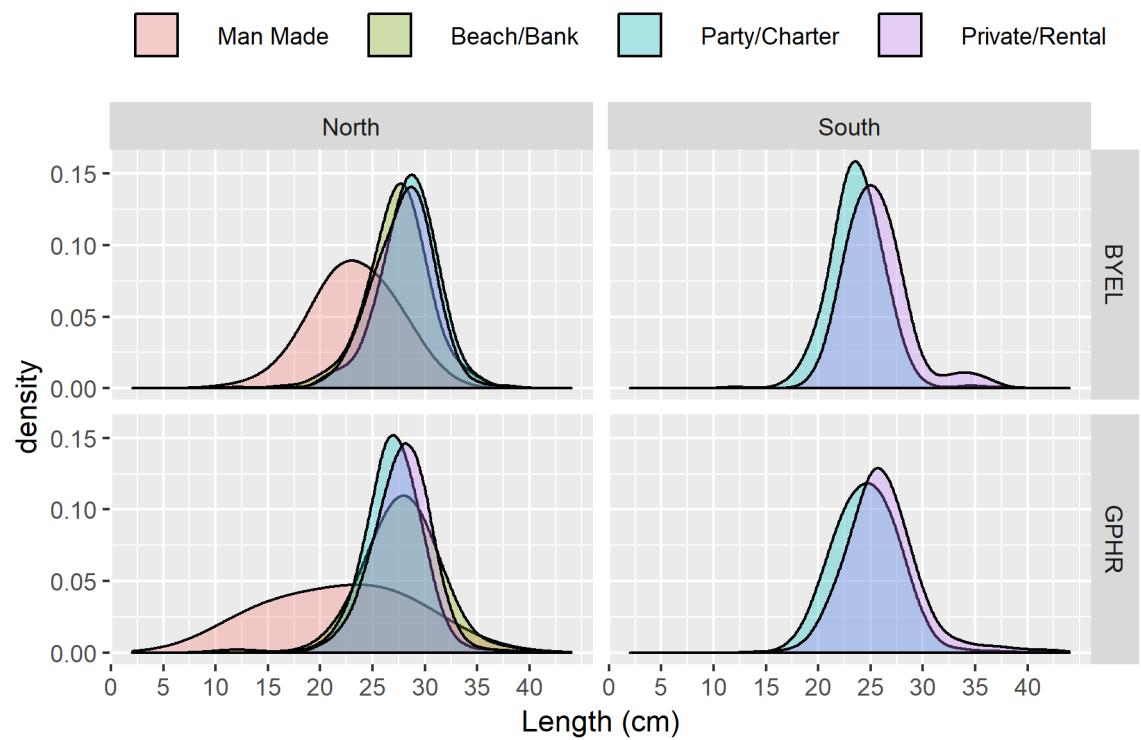

Figure 45: Length distributions of gopher and black-and-yellow rockfish for the recreational fleet north and south of Point Conception and by mode. fig:Rec_lengths_justification

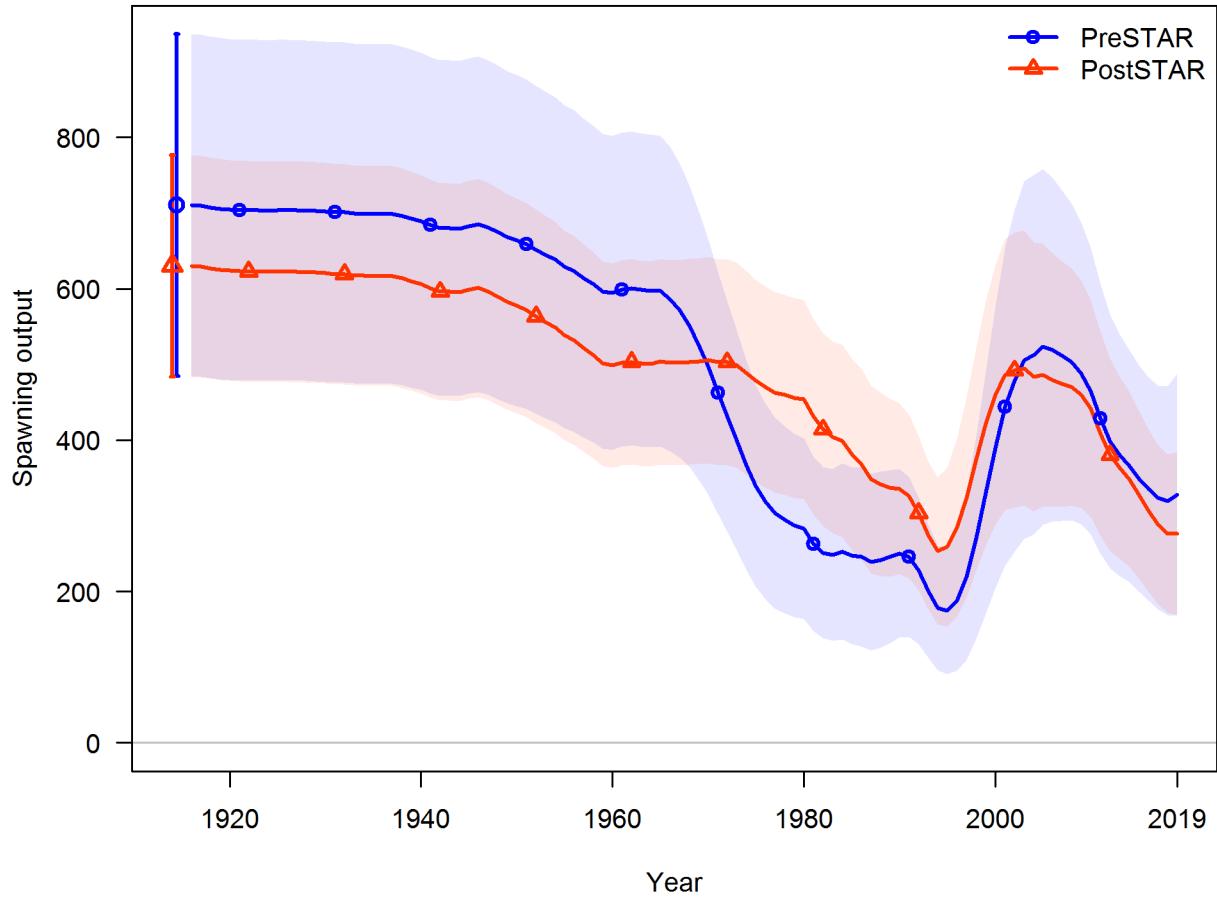

Figure 46: Comparison of the spawning output between the pre-STAR panel base model and the post-STAR model base. [fig:preSTAR_postSTAR_compare_spawnbio](#)

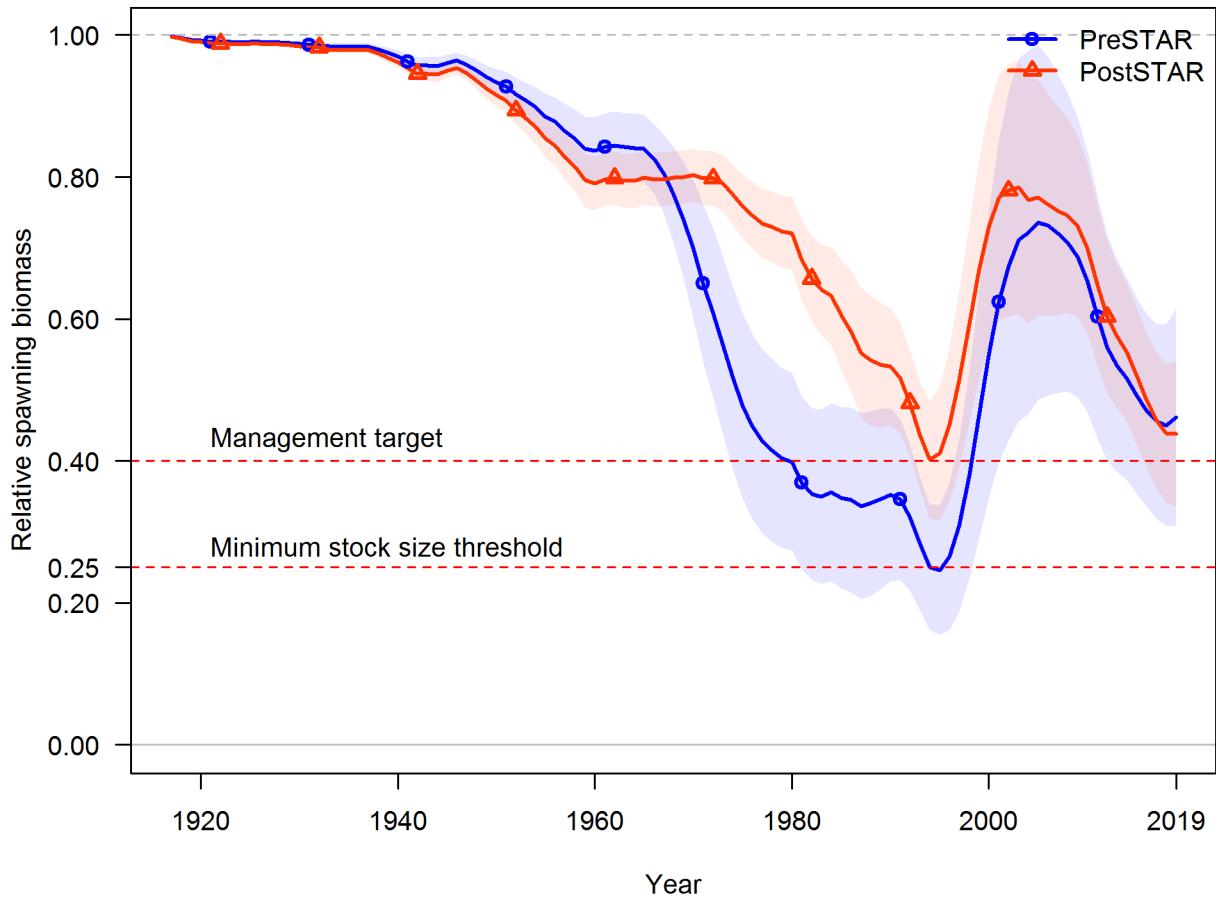

Figure 47: Comparison of the relative spawning output (depletion) between the pre-STAR panel base model and the post-STAR model base. [fig:preSTAR_postSTAR_compare_Bratio](#)
