⁹⁶ **Executive Summary**

⁹⁷ **Stock**

⁹⁸ This assessment reports the status of the gopher and black-and-yellow rockfish
⁹⁹ complex (GBYR, *Sebastodes carnatus/Sebastodes chrysomelas*) resource as in U.S. waters off the
¹⁰⁰ coast of the coast of California south of 40°10' N. latitude (Cape Mendocino) using data
¹⁰¹ through 2018. Both gopher and black-and-yellow rockshes are most abundance north of
¹⁰² Point Conception and are rare north of Sonoma. The range of gopher rockfish extends to
¹⁰³ Baja California, but the black-and-yellow rockfish are rare south of Point Conception.

¹⁰⁴ **Catches**

¹⁰⁵ Information on historical landings of GBYR are available back to 1916 (Table [a](#)). The
¹⁰⁶ recreational fleet began ramping up in the 1950s and has fluctuated over the the last 50 years
¹⁰⁷ (Figure [a](#)). The majority of gopher and black-and-yellow rockfish recreational landings are
¹⁰⁸ from north of Point Conception.

¹⁰⁹ Commercial landings were small during the years of World War II, ranging between 4 to
¹¹⁰ 28 metric tons (mt) per year (Figure [b](#)). The commercial landings increased aftter World
¹¹¹ War II and show periods of cyclical catch for gopher and black-and-yellow rockfishes. The
¹¹² commercial live fish fishery began in the early 1990s, with the first reported live landings
¹¹³ in 1993. Since then the commercial catch has been dominated by the live fish fishery, with
¹¹⁴ minimal landings of dead gopher or black-and-yellow rockfishes. Esimates of total mortality
¹¹⁵ of commercial discards was available starting in 2004, and were estimated prior to then. The
¹¹⁶ landings aggregated by fleets modeled in this assessment can be found in Figure [c](#).

¹¹⁷ Since 2000, annual total landings of GBYR have ranged between 70-169 mt, with landings
¹¹⁸ in 2018 totaling 92 mt.

Figure a: Catch history of GBYR for the recreational fleet.

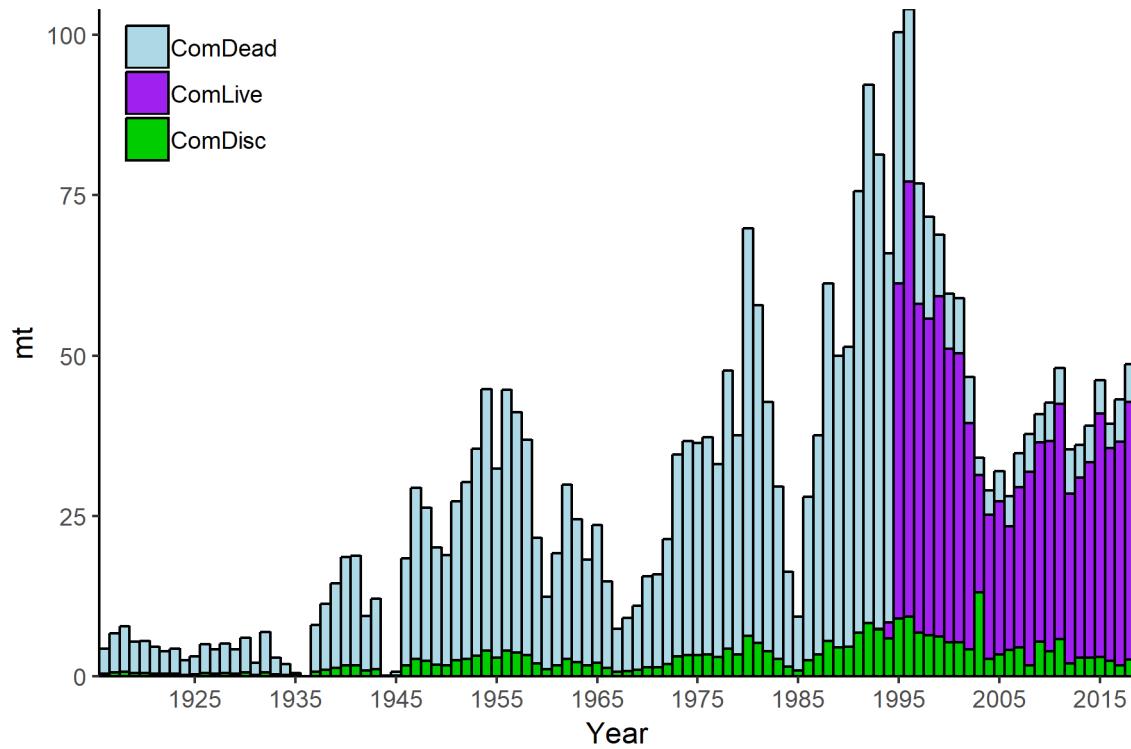

Figure b: Catch history of GBYR for the commercial fleet by dead and live landings, and discards. Catches in 1936 and 1946 were minimal.

Table a: Recent GBYR landings (mt) by fleet.

Year	Commercial Retained	Commercial Discard	Recreational North	Recreational South	Total
2009	35.62	5.38	65.64	4.30	110.93
2010	38.83	3.92	106.76	3.90	153.41
2011	42.39	5.72	76.16	10.24	134.52
2012	33.55	1.93	48.25	9.89	93.62
2013	33.45	2.85	38.43	8.86	83.59
2014	36.40	2.85	56.96	9.06	105.27
2015	43.25	2.93	58.09	5.00	109.27
2016	36.96	2.42	65.72	6.57	111.67
2017	42.04	1.65	49.36	11.15	104.19
2018	47.00	2.54	36.48	6.30	92.32

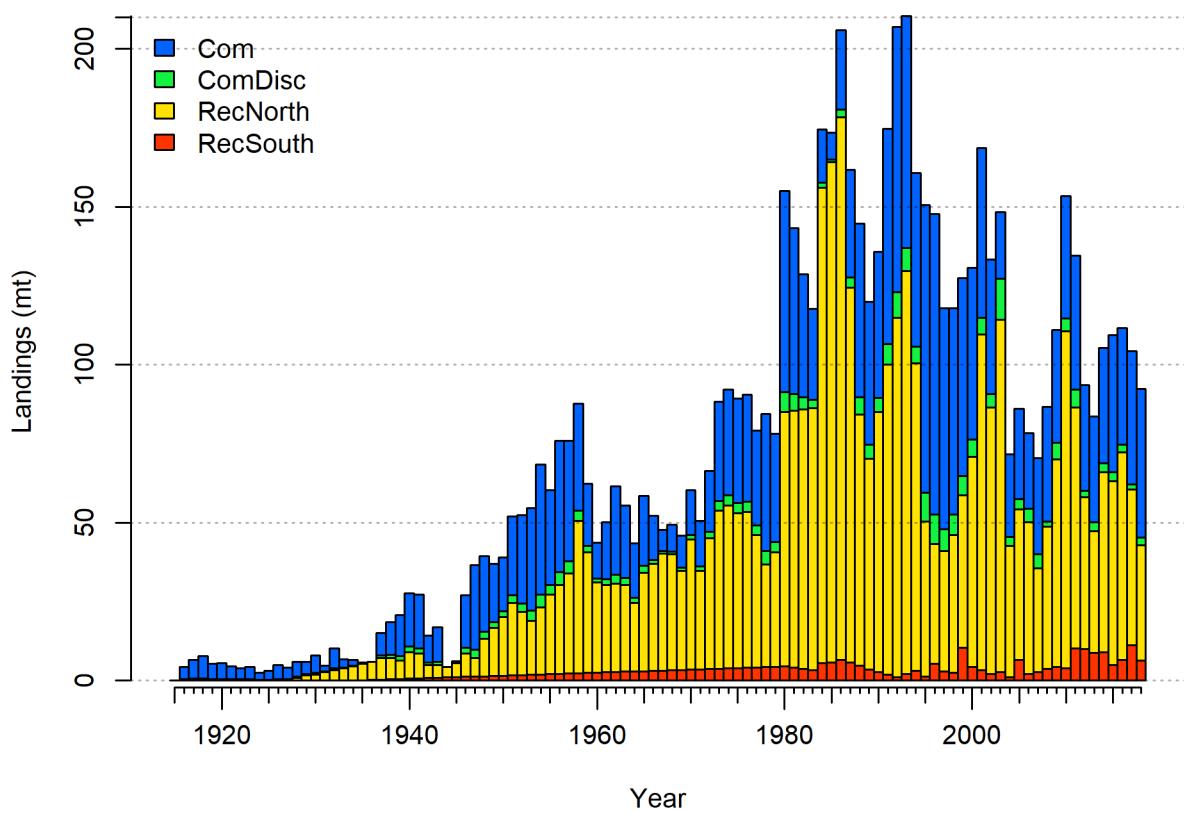

Figure c: Catch history of GBYR in the model.

¹¹⁹ **Data and Assessment**

¹²⁰ This is the first full assessment to include data for black-and-yellow rockfish. Black-and-
¹²¹ yellow rockfish was assessed coastwide as a data poor species using Depletion-Based Stock
¹²² Reduction Analysis (DB-SRA) (Dick and MacCall [2010](#)). The DB-SRA model assigned a
¹²³ 40% probability that the then recent (2008-2009) catch exceeded the 2010 OFL.

¹²⁴ Gopher rockfish south of Point Conception was assessed as a data poor species in 2010 (Dick
¹²⁵ and MacCall [2010](#)). A Depletion-Corrected Average Catch (DCAC) model was used due to
¹²⁶ time constraints. The mean yield from the DCAC distribution was 25.5 mt.

¹²⁷ Gopher rockfish north of Point Conception ($34^{\circ}27'$ N. latitude) was first assessed a full stock
¹²⁸ assessment in 2005 (Key et al. [2005](#)) using SS2 (version 1.19). The assessment was sensitive
¹²⁹ to the CPVF onboard observer index of abundance (referred to as Deb Wilson-Vandenbergs
¹³⁰ onboard observer index in this assessment). The final decision table was based around the
¹³¹ emphasis given to the index, with a value of 5 given a 40% probability and used in the
¹³² baseline model. The stock was found to be at 97% depletion.

¹³³ This assessment incorporates the area south of Point Conception, which was previously
¹³⁴ excluded from the 2005 assessment (Figure [d](#)). The length composition data suggested that
¹³⁵ while the lengths of gopher and black-and-yellow rockfish were similar, fish encountered
¹³⁶ south of Point Conception were smaller. The recreational catches from the man made mode
¹³⁷ are negligible and did not influence the decision to split the fleet at Point Conception. The
¹³⁸ similarity of the length distributions between species and among modes within a region were
¹³⁹ similar and justified one recreational fleet.

¹⁴⁰ This stock assessment retains a single fleet for the commercial fishery, and also includes a
¹⁴¹ commercial discard fleet. Data on commercial discards were not available for and not in-
¹⁴² cluded in the 2005 assessment. The decision to retain one commercial fleet was made by
¹⁴³ examining the length distributions across species, fishing gears, and space, i.e., north and
¹⁴⁴ south of Point Conception. There is very little difference between the length composition
¹⁴⁵ of gopher and black-and-yellow rockfish landed in the commercial fleet north of Point Con-
¹⁴⁶ ception, which contributed 97% of the commercial landings from 1978-2018. The length
¹⁴⁷ distributions suggest that gopher rockfish south of Point Conception landed dead south of
¹⁴⁸ Point Conception are slightly smaller on average than north of Point Conception. How-
¹⁴⁹ ever, there is not enough data available to justify splitting the commercial fishery north and
¹⁵⁰ south of Point Conception. The length compositions of discarded fish are small in all of the
¹⁵¹ subplots, suggesting size-based discarding. Because Stock Synthesis is not set up to handle
¹⁵² depth-dependent discard mortality rates and we're modelling two species as a complex with
¹⁵³ differing depth-dependent discard mortality rates, the time series of commercial discards was
¹⁵⁴ incorporated as a fleet.

¹⁵⁵ A number of sources of uncertainty are now addressed in this assessment. This assessment
¹⁵⁶ includes length data, estimated growth, an updated length-weight curve, an update maturity
¹⁵⁷ curve, a number of new indicies, and new conditional length at age data.

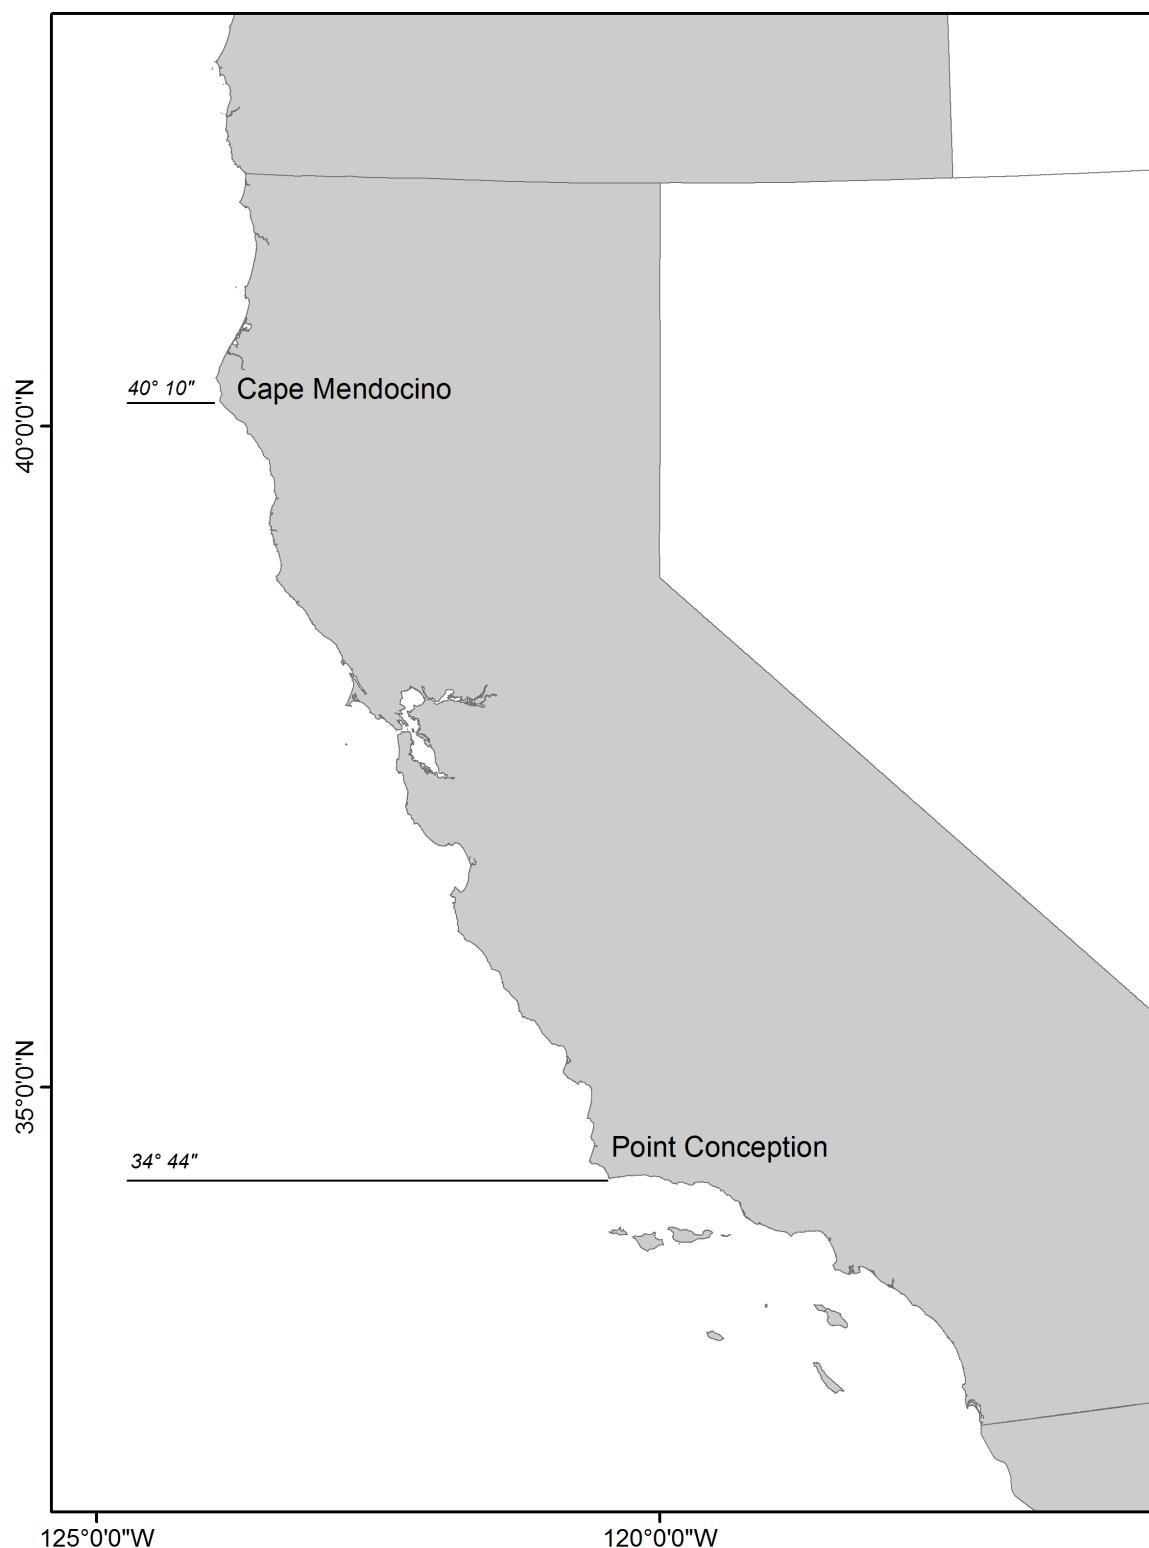

Figure d: Map depicting the core distribution of gopher and black-and-yellow rockfishes. The stock assessment is bounded at Cape Mendocino in the north to the U.S./Mexico border in the south.

158 **Stock Biomass**

159 The predicted spawning biomass from the base model generally showed a slight decline prior
160 to 1962, when the early recruitment deviations were first estimated (Figure e and Table b).
161 The stock declined from 1967 to 1995, followed by a period increase from 1996 to 2005. From
162 2005-2018 the stock has been in decline, although leveled spawning biomass has been rela-
163 tively level since 2017. The 2018 estimated spawning biomass relative to unfished equilibrium
164 spawning biomass is above the target of 40% of unfished spawning biomass at 4 620% (95%
165 asymptotic interval: $\pm 3\ 080\% - 6\ 150\%$) (Figure f). Approximate confidence intervals based
166 on the asymptotic variance estimates show that the uncertainty in the estimated spawning
167 biomass is high.

Table b: Recent trend in beginning of the year spawning output and depletion for the model for GBYR.

Year	Spawning Output (million eggs)	~ 95% confidence interval	Estimated depletion	~ 95% confidence interval
2010	929	550 - 1308	65.36	47 - 83.72
2011	857	500 - 1213	60.28	43.17 - 77.39
2012	796	460 - 1132	56.00	40.01 - 71.99
2013	760	441 - 1079	53.47	38.48 - 68.47
2014	733	426 - 1039	51.55	37.35 - 65.76
2015	699	401 - 997	49.18	35.44 - 62.92
2016	671	376 - 965	47.18	33.59 - 60.77
2017	648	353 - 944	45.60	31.87 - 59.34
2018	640	337 - 942	45.01	30.78 - 59.24
2019	656	336 - 977	46.18	30.85 - 61.5

Spawning output with ~95% asymptotic intervals

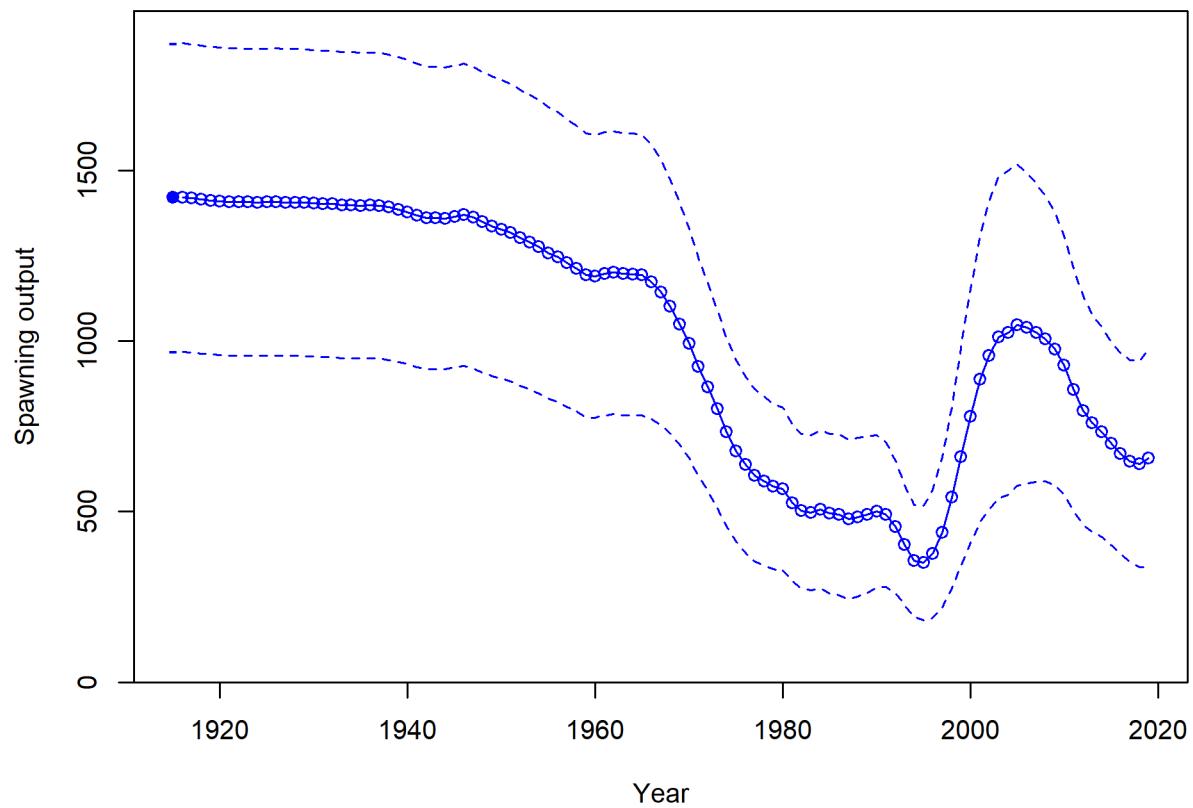

Figure e: Time series of spawning biomass trajectory (circles and line: median; light broken lines: 95% credibility intervals) for the base case assessment model.

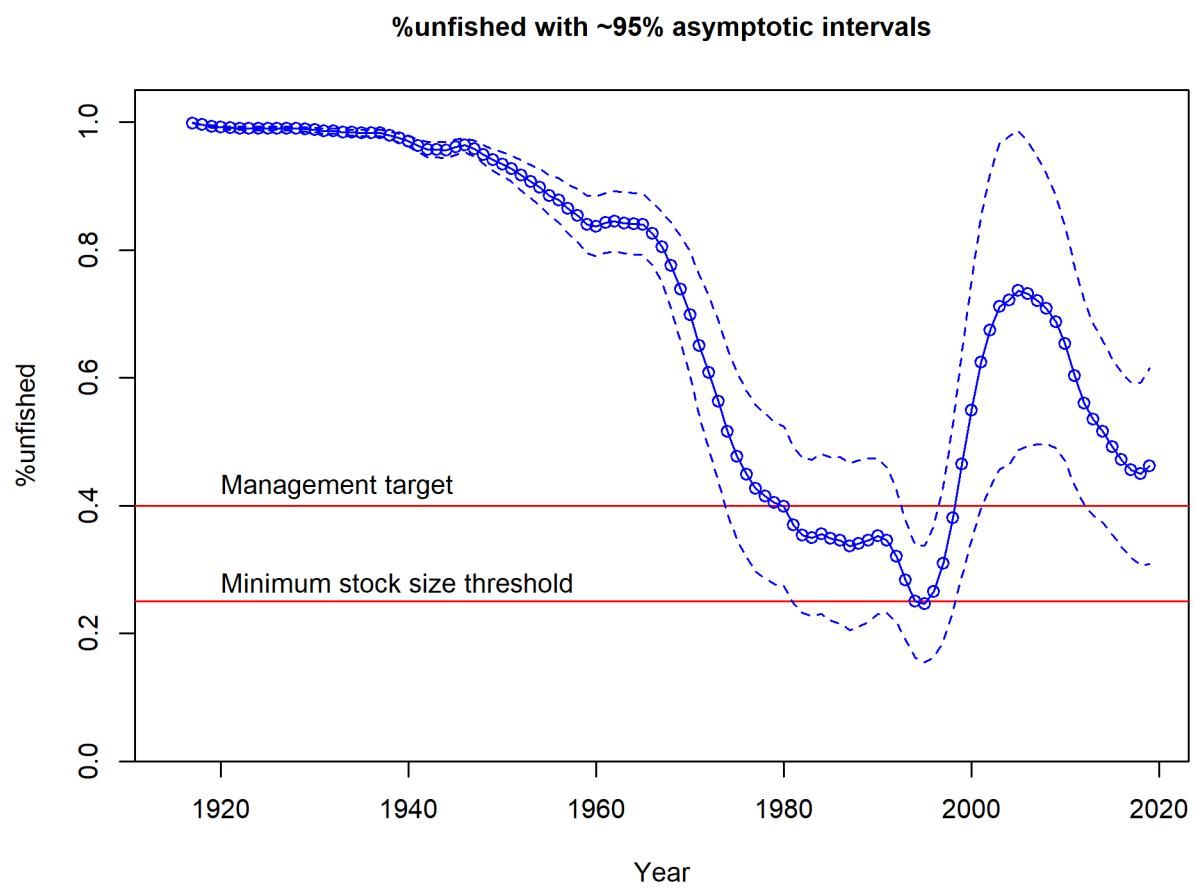

Figure f: Estimated percent depletion with approximate 95% asymptotic confidence intervals (dashed lines) for the base case assessment model.

¹⁶⁸ **Recruitment**

¹⁶⁹ Recruitment deviations were estimated from 1979-2018 (Figure [g](#) and Table [c](#)). There are
¹⁷⁰ estimates of strong recruitment in the late 1990s, and also from 2013-2015, which peaked in
¹⁷¹ 2015.

Table c: Recent recruitment for the GBYR assessment.

Year	Estimated Recruitment (1,000s)	~ 95% confidence interval
2010	4096	1467 - 11441
2011	3460	1197 - 10005
2012	3465	1168 - 10282
2013	4497	1524 - 13264
2014	7879	2709 - 22910
2015	11760	4041 - 34227
2016	8732	2924 - 26076
2017	5727	1826 - 17959
2018	4333	1339 - 14024
2019	4624	1396 - 15319

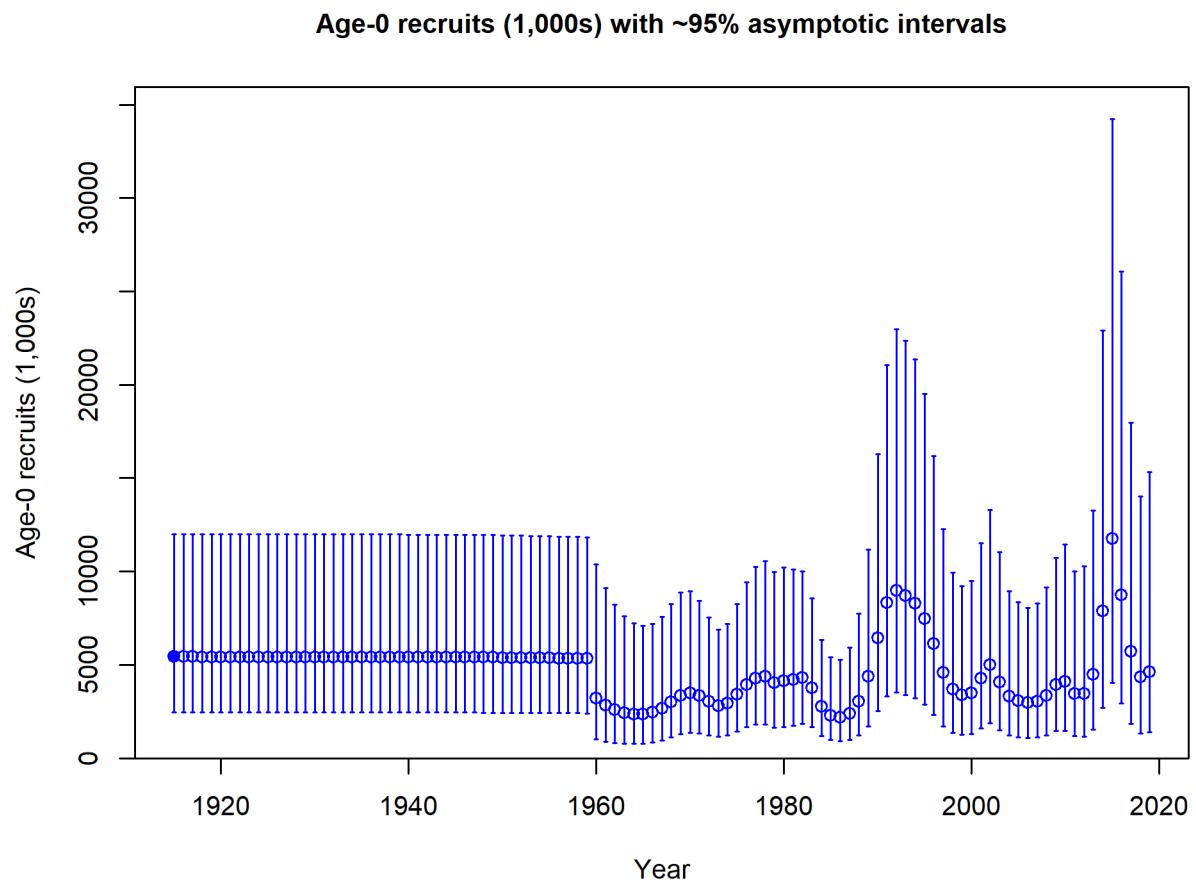

Figure g: Time series of estimated GBYR recruitments for the base-case model with 95% confidence or credibility intervals.

¹⁷² **Exploitation status**

¹⁷³ Harvest rates estimated by the base model exceeded management target levels durin a num-
¹⁷⁴ ber of years in the 1990s. (Table [d](#) and Figure [h](#)). Recent harvest over the last decade
¹⁷⁵ increased until 2016-2017 to 0.70 and decreased to 0.66 in 2018. The estimated relative
¹⁷⁶ depletion is currently greater than the 40% unfished spawning output target. Recent ex-
¹⁷⁷ ploitation rates on GBYR were predicted to be significantly below target levels.

Table d: Recent trend in spawning potential ratio and exploitation for GBYR in the model. Fishing intensity is (1-SPR) divided by 50% (the SPR target) and exploitation is F divided by F_{SPR} .

Year	Fishing intensity	~ 95% confidence interval	Exploitation rate	~ 95% confidence interval
2009	0.56	0.33 - 0.78	0.07	0.04 - 0.09
2010	0.69	0.44 - 0.94	0.10	0.06 - 0.14
2011	0.68	0.43 - 0.93	0.09	0.06 - 0.13
2012	0.57	0.34 - 0.81	0.07	0.04 - 0.1
2013	0.55	0.32 - 0.78	0.06	0.04 - 0.09
2014	0.65	0.4 - 0.89	0.08	0.05 - 0.11
2015	0.68	0.42 - 0.93	0.08	0.05 - 0.12
2016	0.71	0.45 - 0.97	0.08	0.04 - 0.12
2017	0.71	0.44 - 0.98	0.07	0.04 - 0.11
2018	0.67	0.41 - 0.94	0.06	0.03 - 0.09

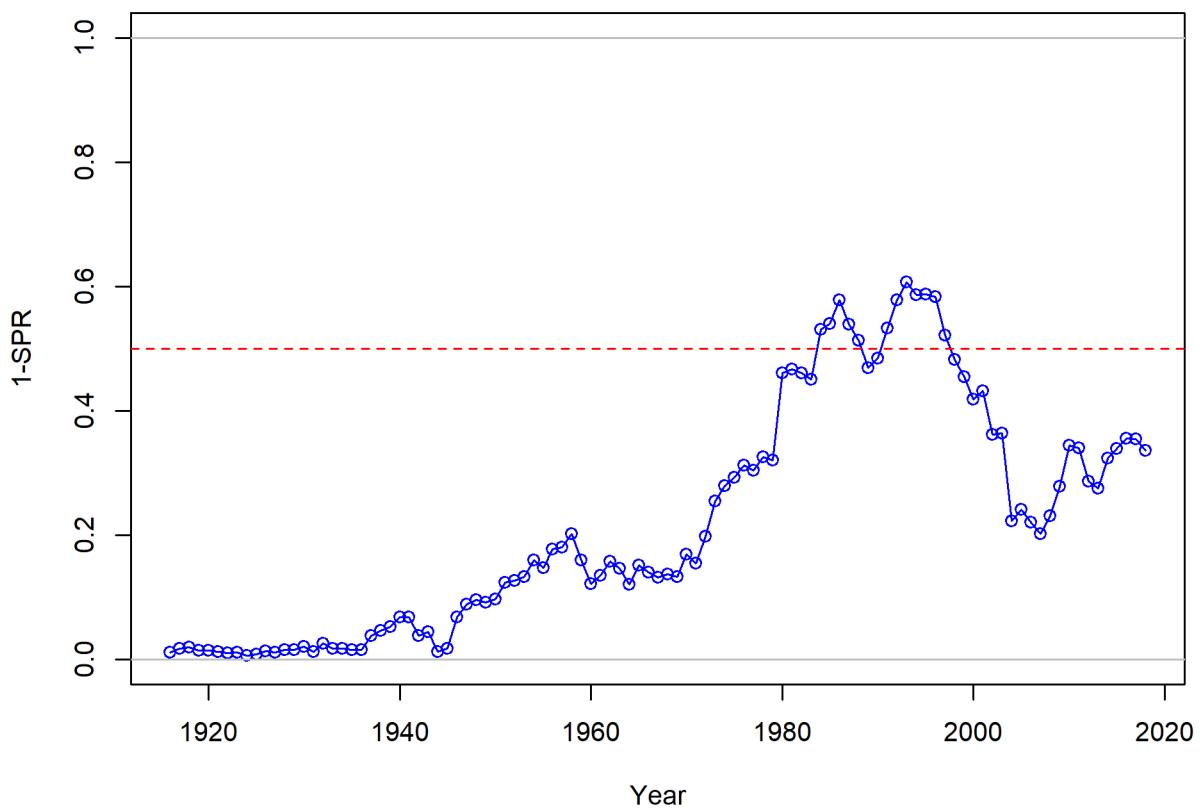

Figure h: Estimated spawning potential ratio (SPR) for the base-case model. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the SPR_{50%} harvest rate. The last year in the time series is 2018.

¹⁷⁸ **Ecosystem Considerations**

¹⁷⁹ In this assessment, ecosystem considerations were not explicitly included in the analysis.
¹⁸⁰ This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)
¹⁸¹ that could contribute ecosystem-related quantitative information for the assessment.

¹⁸² **Reference Points**

¹⁸³ This stock assessment estimates that GBYR in the model is above the biomass target
¹⁸⁴ ($SB_{40\%}$), and well above the minimum stock size threshold ($SB_{25\%}$). The estimated rel-
¹⁸⁵ ative depletion level for the base model in 2019 is 4 620% (95% asymptotic interval: ± 3
¹⁸⁶ 080% - 6 150%, corresponding to an unfished spawning biomass of 656 million eggs (95%
¹⁸⁷ asymptotic interval: 336 - 977 million eggs) of spawning biomass in the base model (Table
¹⁸⁸ e). Unfished age 1+ biomass was estimated to be 2,361 mt in the base case model. The
¹⁸⁹ target spawning biomass ($SB_{40\%}$) is 569 million eggs, which corresponds with an equilibrium
¹⁹⁰ yield of 200 mt. Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to $SPR_{50\%}$
¹⁹¹ is 186 mt (Figure i).

Table e: Summary of reference points and management quantities for the base case model.

Quantity	Estimate	Low 2.5% limit	High 2.5% limit
Unfished spawning output (million eggs)	1,421	969	1,874
Unfished age 1+ biomass (mt)	2,361	1,755	2,966
Unfished recruitment (R_0)	5,426	933	9,920
Spawning output(2018 million eggs)	640	337	942
Depletion (2018)	0.45	0.308	0.592
Reference points based on SB_{40%}			
Proxy spawning output ($B_{40\%}$)	569	448	689
SPR resulting in $B_{40\%}$ ($SPR_{B40\%}$)	0.458	0.458	0.458
Exploitation rate resulting in $B_{40\%}$	0.152	0.103	0.202
Yield with $SPR_{B40\%}$ at $B_{40\%}$ (mt)	200	108	291

Dead Catch MSY (mt)	236	122	351
Retained Catch MSY (mt)	236	122	351

192 Management Performance

193 Gopher and black-and-yellow rockfishes are managed as part of the minor nearshore complex
 194 in the groundfish Fishery Management Plan. The total mortality of the minor nearshore
 195 rockfish has been below the ACL in all years (2011-2016). Total mortality estimates from
 196 the NWFSC are not yet available are not yet available for 2017-2018. GBYR total mortality
 197 was on average 20% of the total minor nearshore rockfish total mortality from 2011-2016. A
 198 summary of these values as well as other base case summary results can be found in Table f.

199 Unresolved Problems and Major Uncertainties

Table f: Recent trend in total mortality for gopher and black-and-yellow rockfishes (GBYR), combined, relative to the management guidelines for the minor nearshore rockfish south of 40°10' N. latitude. Total mortality estiamtes are based on annual reports from the NMFS NWFSC

Year	GBYR	Minor Nearshore Rockfish		
	Total mortality	Total mortality	ACL	OFL
2011	122.87	436	1,001	1,156
2012	91.96	445	1,001	1,145
2013	104.53	495	990	1,164
2014	103.63	596	990	1,160
2015	107.95	676	1,114	1,313
2016	111.55	641	1,006	1,288
2017	-	-	1,329	1,163
2018	-	-	1,344	1,179

²⁰⁰ **Decision Table**

²⁰¹ This section will be completed after the STAR panel.

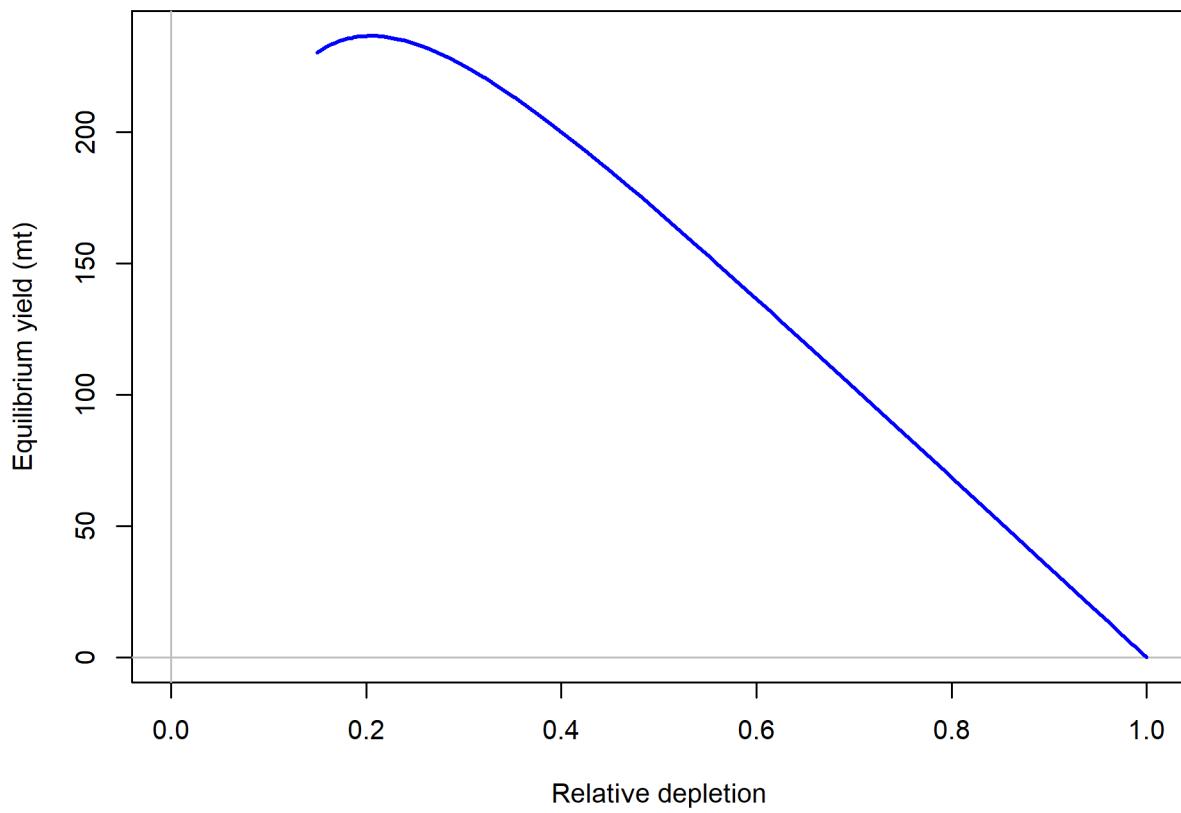

Figure i: Equilibrium yield curve for the base case model. Values are based on the 2018 fishery selectivity and with steepness fixed at 0.718.

²⁰² **Research and Data Needs**

²⁰³ This section will be completed after the STAR panel.

204 **1 Introduction**

205 **1.1 Basic Information and Life History**

206 *Population Structure and Complex Assessment Considerations*

207 There have been a number of analyses conducted on the genetic differentiation between go-
208 pher rockfish and black-and-yellow rockfish. The studies have yielded some range of results,
209 but have generally concluded that there is unusually low genetic differentiation between the
210 two species. The most frequently used measure of genetic analyses to evaluate evidence for
211 population differentiation is the fixation index (F_{ST}), defined as the proportion of the total
212 genetic variation in one sub-population (subscript S) relative to the total genetic variation
213 (subscript T) (Hauser and Carvalho 2008, Waples et al. 2008). Values of F_{ST} range from
214 0 to 1 where a zero value implies the populations are panmictic and a value closer to one
215 implies the two populations are genetically independent. Values of F_{ST} thought to be consis-
216 tent with biologically meaningful genetic differentiation and demographic isolation between
217 populations range from 0.05 to 0.1 (Waples and Gaggiotti 2006). It is also important to
218 note that F_{ST} values are dependent on the study's sample size and it may not necessarily be
219 appropriate to compare them across studies.

220 Morphologically, gopher and black-and-yellow rockfishes are almost indistinct, except for
221 their color variation (Hubbs and Schultz 1933). Early efforts to evaluate whether the two
222 species were genetically distinct began with an allozyme analysis by Seeb et al. (1986),
223 which did not detect genetic differentiation between gopher and black-and-yellow rockfish.
224 However, as allozymes are proteins that are often conserved, this early work was not neces-
225 sarily representative of genome-wide relationships between the two groups. In a subsequent
226 study of restriction site polymorphisms, Hunter et al. (1994) found slight but significant
227 differences between species based on restriction fragment length polymorphisms (RFLP's).
228 Following that study, an analysis of the mitochondrial control region by Alesandrini and
229 Bernardi (1999) did not detect differences between the two species, although mtDNA also
230 has limitations regarding how results can be extrapolated across the nuclear genome. Anal-
231 ysis of seven microsatellite loci by Narum et al. (2004) found an F_{ST} of 0.049 across the
232 overlapping range of the two species, which provided some evidence of divergence, although
233 such divergence is relatively low compared to other species within *Sebastes*. Those authors
234 characterized their results as suggesting that the two are “reproductively isolated incipient
235 species.” Buonaccorsi et al. (2011) found an even lower F_{ST} of 0.01 using 25 microsatellite
236 loci, and concluded that gopher and black-and-yellow rockfish “have not completed the spe-
237 ciation process.” All of these studies are indicative of low levels of genetic divergence and a
238 high probability of ongoing gene flow between the two nominal species.

239 Most recently, an analysis of rockfish species assignment using microhaplotypes by Baetscher
240 (2019) observed mistaken genetic assignment of a small number of individuals between go-
241 pher and black-and-yellow rockfishes, while no other species among the 54 rockfishes analyzed

242 resulted in mis-assignments. In addition, comparisons of F_{ST} values within the study indicated
243 that the level of genetic differentiation observed between gopher and black-and-yellow
244 rockfishes is lower than that observed among all other pairwise comparisons of the 54 species
245 in the *Sebastodes* genus that were included in their analysis. Baetscher (2019) characterized the
246 results as suggestive of the two species representing “sister species with evidence of ongoing
247 gene flow,” noting that a more rigorous evaluation of the level of genetic distinction between
248 these two species would benefit from whole-genome sequencing of representatives from each
249 species group.

250 In addition to the differences in coloration, the depth distribution and range differ between
251 the two species. The range of both species extends from Cape Blanco Oregon to Baja
252 California. Both species are uncommon north of Fort Bragg, California and black-and-yellow
253 rockfish is uncommon south of Point Conception, California. However, gopher rockfish can
254 be found as far south as Punta San Roque on the Baja peninsula. Gopher rockfish are found
255 in rocky reef habitat from the intertidal to depths of 264 ft (80 m) with a predominant depth
256 distribution of 30 to 120 ft (9-37 m), while the black-and-yellow rockfish occupies depths
257 from the intertidal to 120 ft (40 m) and is predominantly observed in depths shallower than
258 60 ft (18 m) (Eschmeyer et al. 1983, Love et al. 2002).

259 Both species are solitary, sedentary, and territorial species with home ranges of 10-12 square
260 meters (Love et al. 2002). A large percentage (67-71%) of black-and-yellow rockfish returned
261 to the site of capture within two weeks after translocated within 50 m (Hallacher 1984). Lea
262 et al. (1999) found that gopher rockfish exhibit minor patterns of movement (<12.8 km)
263 with all fish being recaptured on the same reef system where they were tagged. Matthews
264 (1985) found that 11.8% of tagged and recaptured gopher rockfish, and 25% of black-and-
265 yellow rockfish, moved from four low-relief natural reefs to a new high-relief artificial reef
266 in Monterey Bay. The maximum distance between the natural and artificial reefs traveled
267 by gopher or black-and-yellow rockfish was 1.6 km. After only a year, the fish assemblage
268 on the artificial reef closely resembled that of the nearby natural reefs. The paper did no
269 address the spatial segregation of gopher and black-and-yellow rockfish on the new artificial
270 reef.

271 Larson (1980) conducted a study on the territoriality and segregation between gopher and
272 black-and-yellow rockfishes. When one species was removed, the other extended its depth
273 range to areas where the other previously occupied, indicating inter-specific competition
274 plays a role in controlling their depth distributions where both species are present. Of the
275 two species, black-and-yellow rockfish are socially dominant and aggressive towards excluding
276 gopher rockfish from shallower waters.

277 Both species are be feed at night, with similar diets composed primarily of crabs and
278 shrimp, supplemented by fish and cephalopods (Larson 1972, 1985, Love et al. 2002). Loury
279 et al. (2015) found no significant differences in the diet of gopher rockfish inside and outside
280 the 35 year old Point Lobos Marine Protected Area (MPA). She did find the diet of gopher
281 rockfish at Año Nuevo (shallower and north of Point Lobos) was dominated by crabs and
282 dominated by brittle stars at southern, deeper study locations. Zuercher (2019) examined

283 the diets of a suite of nearshore rockfish species including black-and-yellow and found that
284 they relied on hard-bodied benthic invertebrates such as Brachyuran crabs, shrimps, other
285 arthropods, and octopus. The diet of black-and-yellow rockfish remained the same across
286 sampling years, but they occupied a lower trophic level during the upwelling season.

287 1.2 Early Life History

288 Gopher and black-and-yellow rockfish have similar juvenile development. Both rockfish
289 species are viviparous and release one brood per season between January and July (Echev-
290 erria 1987). Larvae are approximately 4 mm in length at birth and have a 1-2 month pelagic
291 stage before recruiting to the kelp forest canopy, i.e., surface fronds of *Macrosystis pyrifera*
292 and *Cystoseira osmundacea* at around 15-21 mm (Anderson 1983, Wilson et al. 2008).
293 The larvae are transparent until they reach juvenile stage at 22-23 mm. Differences in col-
294 oration between the two species begin to occur at 25-30 mm and can be used to identify one
295 species from the other. Gopher rockfish become more orange and brown, while black-and-
296 yellow rockfish become more black and yellow. Benthic juveniles associate with *Macrosystis*
297 holdfasts and sporophylls (Anderson 1983).

298 The juveniles undergo ontogenetic migration down the stalks to deeper depths, finally settling
299 on rocky reef habitat in their respective adult depth distribution. Juvenile bocaccio and other
300 fish predate on young of year and other reef dwelling species including cabezon predate on
301 post-settlement juveniles. Individuals avoid rough surge conditions and predators by hiding
302 in the rocky bottom during the daylight hours, then returning to more open water at dusk
303 (Love et al. 2002).

304 1.3 Map

305 A map showing the scope of the assessment and depicting boundaries at Cape Mendocino
306 to the north and the U.S./ Mexico border at the south (Figure 1). The recreational fishing
307 fleet was split into two fleets at Point Conception.

308 1.4 Ecosystem Considerations

309 In this assessment, ecosystem considerations were not explicitly included in the analysis.
310 This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)
311 that could contribute ecosystem-related quantitative information for the assessment.

312 **1.5 Fishery Information**

313 The hook-and-line fishery off California developed in the late 19th century (Love et al. 2002).

314 The rockfish trawl fishery was established in the early 1940s, when the United States became
315 involved in World War II and wartime shortage of red meat created an increased demand
316 for other sources of protein (Harry and Morgan 1961, Alverson et al. 1964).

317 Gopher and black-and-yellow (referred to from hereon as GBYR when discussing the com-
318 plex) rockfish have been a minor component of the commercial and recreational rockfish
319 fishery since at least the late 1960s (CFIS and RecFIN). The commercial catch histories
320 of the two species cannot easily be separated (Figure 2). From 1916-1936 only black-and-
321 yellow rockfish were reported in the landings, and an average of 0.04 mt of black-and-yellow
322 rockfish are reported from 1937-1983. Black-and-yellow rockfish reappear in the landings in
323 1984 with 7.2 mt landed commercially. From 1985-1988 the trend switches and only black-
324 and-yellow rockfish appear in the commercial landings, with gopher rockfish averaging 0.1
325 mt landed, and 0 mt reported in 1987. From 1988 and on, the landings are dominated by
326 gopher rockfish, and both species are represented in the commercial landings.

327 The landings from south of Point Conception are minor throughout the time period, with
328 peaks in the 1950s and 60s for gopher rockfish. Black-and-yellow rockfish are rare south of
329 Point Conception and expected that these catches are minimal.

330 The live fish fishery began in the early 1990s, with the first reported commercial landings of
331 live gopher rockfish in 1993, and black-and-yellow rockfish a year later. By 1995 over half
332 (57%; 39 mt) of the commercial landings were from the live fish fishery. This increased quickly
333 over the next few years and has been on average 84% of the landed gopher and black-and-
334 yellow rockfish (also referred to GBYR to reference the complex in this assessment) since
335 2000. The majority of the landings are from gopher rockfish north of Point Conception.
336 Landings of live GBYR south of Point Conception were higher in the late 1990s, (max. 3.2
337 mt in 1999), and have been averaging 0.4 mt since 2003.

338 The ex-vessel value of GBYR increased from less than \$40,000 in 1984 and peaked at \$680,452
339 in 1996 (Figure 3). The ex-vessel revenue has been fairly stable at around \$500,000 a year
340 since 2007. Prior to the live fish fishery in 1994, the average price per pound for either
341 species was around \$2 a pound. The live fish fishery increased the value of both species to
342 an average of \$6-\$8 a pound. The maximum reported value of either a gopher or black-and-
343 yellow rockfish was \$20 a pound in 2003.

344 The recreational GBYR fishery for California is most prominent north of Point Conception
345 throughout the entire catch history (Figure a). The recreational landings increased from
346 1928 to 1980. The sharp increase in the 1980s could be an artifact of the MRFSS sampling
347 program that began in 1980; however, the more recent recreational landings also exhibit a
348 cyclical trend of years with high catches followed by period of decreased recreational landings.
349 The CRFS era recreational total mortality represents the most accurate description of the
350 recreational fleet's catches in terms of area, mode and species (Figure 4).

351 Recreational GBYR catches are dominated by gopher rockfish north of Point Conception in
352 the private/rental (PR) and party/charter (PC or CPFV) modes. South of Point Conception
353 gopher rockfish are predominately caught by the CPFV fleet, with all other modes being
354 insignificant. The total recreational mortality of black-and-yellow rockfish south of Point
355 Conception since 2005 is 3 mt, compared to 106 mt north of Point Conception. The total
356 mortality since 2005 for gopher rockfish is 86 mt south of Point Conception and 669 mt north
357 of Point Conception.

358 1.6 Summary of Management History

359 Prior to the adoption of the Pacific Coast Groundfish Fishery Management Plan (FMP)
360 in 1982, GBYR were managed through a regulatory process that included the California
361 Department of Fish and Wildlife (CDFW) along with either the California State Legislature
362 or the Fish and Game Commission (FGC) depending on the sector (recreation or commercial)
363 and fishery. With implementation of the Pacific Coast Groundfish FMP, GBYR came under
364 the management authority of the Pacific Fishery Management Council (PFMC), and were
365 managed as part of the *Sebastodes* complex. Because neither species had undergone rigorous
366 stock assessment and did not compose a large fraction of the landings they were classified
367 and managed as part of “Remaining Rockfish” under the larger heading of “Other Rockfish”
368 (PFMC ([2002](#), [2004](#))).

369 Since the early 1980s a number of federal regulatory measures have been used to manage
370 the commercial rockfish fishery including cumulative trip limits (generally for two- month
371 periods) and seasons. Starting in 1994 the commercial groundfish fishery sector was divided
372 into two components: limited entry and open access with specific regulations designed for
373 each component. Other regulatory actions for the general rockfish categories have included
374 area closures, gear restrictions, and cumulative bimonthly trip limits set for the four different
375 commercial sectors - limited entry fixed gear, limited entry trawl, open access trawl, and open
376 access non-trawl. Harvest guidelines are also used to regulate the annual harvest for both
377 the recreational and commercial sectors.

378 In 2000, changes in the PFMC’s rockfish management structure resulted in the discontinued
379 use of the *Sebastodes* complex, and was replaced with three species groups: nearshore, shelf,
380 and slope rockfishes (January 4, 2000; 65 FR 221), of which GBYR are included in the
381 nearshore group. Within the nearshore group, they are included in the “shallow nearshore
382 rockfish” component.

383 During the late 1990s and early 2000s, major changes also occurred in the way that California
384 managed its nearshore fishery. The Marine Life Management Act (MLMA), which was passed
385 in 1998 by the California Legislature and enacted in 1999, required that the FGC adopt an
386 FMP for nearshore finfish ([Wilson-Vandenberg et al. 2014](#)). It also gave authority to the
387 FGC to regulate commercial and recreational nearshore fisheries through FMPs and provided
388 broad authority to adopt regulations for the nearshore fishery during the time prior to

389 adoption of the nearshore finfish FMP. Within this legislation, the Legislature also included
390 commercial size limits for ten nearshore species including GBYR (10-inch minimum size)
391 and a requirement that commercial fishermen landing these ten nearshore species possess a
392 nearshore permit.

393 Following adoption of the Nearshore FMP and accompanying regulations by the FGC in fall
394 of 2002, the FGC adopted regulations in November 2002 which established a set of marine
395 reserves around the Channel Islands in southern California (which became effective April
396 2003). The FGC also adopted a nearshore restricted access program in December 2002
397 (which included the establishment of a Deeper Nearshore Permit) to be effective starting in
398 the 2003 fishing year.

399 Also, since the enactment of the MLMA, the Council and State in a coordinated effort
400 developed and adopted various management specifications to keep harvest within the harvest
401 targets, including seasonal and area closures (e.g. the CCAs; a closure of Cordell Banks
402 to specific fishing), depth restrictions, minimum size limits, and bag limits to regulate the
403 recreational fishery and license and permit regulations, finfish trap permits, gear restrictions,
404 seasonal and area closures (e.g. the RCAs and CCAs; a closure of Cordell Banks to specific
405 fishing), depth restrictions, trip limits, and minimum size limits to regulate the commercial
406 fishery.

407 The state of California has adopted regulatory measures to manage the fishery based on
408 the harvest guidelines set forth by the PFMC. The commercial open access and limited
409 entry fixed gear sectors have undergone three different spatial management changes in since
410 2000. Since 2005, both have managed the area south of 40°10' N. latitude as one area. The
411 open access commercial fishery is managed based on bimonthly allowable catches, that have
412 ranged from 200 pounds to 1800 pounds per two months since 2000. From 2005 to 2018, the
413 catch limits have doubled and are now set at 1200 pounds per two months (for all months)
414 with March and April remaining closed. The limited entry fixed year sector has followed the
415 same pattern as the open access sector with bi-monthly limits and a doubling of the catch
416 since 2005. The limited entry trawl fleet is managed on monthly limits on an annual basis.
417 Since 2011, the limit has been 300 pounds per month for non-IFQ species. A history of
418 California's commercial regulations from 2000-2018 can be found in [Appendix A](#). A 10-inch
419 total length minimum size limit was implemented in 1999 for both species in the commercial
420 fleet.

421 Significant regulatory changed in California's recreational sector began with a change from
422 unlimited number of hooks and lines allowed in 1999 and prior to no more than three hooks
423 and one line per angler in 2000. Since 2001, the limit has been no more than two hooks and
424 one line per angler. There is no size limit in the recreational fishery for gopher or black-and-
425 yellow rockfish. GBYR are part of the nearshore complex which has had a sub-bag limit
426 within the rockfish bag limit since 1999. The nearshore sub-bag limit has been 10 fish since
427 2005.

428 California also began spatial management, closures, and depth restrictions for the recre-
429 ational fleet in 2000. In general, the recreational season north of Point Conception extends

430 from April to December, and south of Point Conception from March to December. In the
431 area that GBYR are most commonly landed, from Monterey to Morro Bay, the depth restric-
432 tions have been between 30 and 40 fathoms until 2017. In 2017 the depth restrictions were
433 eased by 10 fathoms, opening up fishing depths along the central California coast that had
434 not been open consistently since 2002. In both 2017 and 2018, the deepest 10 fathoms was
435 closed prior to the season in December due to high by-catch rates of yelloweye rockfish, one
436 of two rockfish species that are still overfished. A full history of the recreational regulations
437 relating to the spatial management of the fleet can be found in [Appendix B](#).

438 1.7 Management Performance

439 The contribution of GBYR to the minor nearshore rockfish OFLs is currently derived from
440 two sources: 1) forecasts from Key et al. ([2005](#)), from Cape Mendocino to Point Conception,
441 and 2) a Depletion Corrected Average Catch (DCAC ([MacCall 2009](#))) for the area south of
442 Point Conception. The total mortality of the minor nearshore rockfish has been below the
443 ACL in all years (2011-2016). Total mortality estiamtes from the NWFSC are not yet
444 available are not yet available for 2017-2018. GBYR total mortality was on average 20%
445 of the total minor nearshore rockfish total mortality from 2011-2016. A summary of these
446 values as well as other base case summary results can be found in Table [f](#).

447 1.8 Fisheries Off Mexico or Canada

448 The range of GBYR does not extend north to the Canadian border, and they are rarely
449 encountered in Oregon and Washington. The southern end of the gopher rockfish's range
450 extends to Punta San Roque (southern Baja California) while the southern end of the black-
451 and-yellow rockfish's range extends to Isla Natividad (central Baja California) (Love et al.
452 [2002](#)). However, black-and-yellow rockfish are rare south of Point Conception, California.
453 This was no available information on the fishery for GBYR at the time of this assessment,
454 nor additional details on the abundance or distribution patterns in Mexican waters.

455 2 Assessment

456 2.1 Data

457 Data used in the GBYR assessment are summarized in Figure [5](#). Descriptions of the data
458 sources are in the following sections.

459 **2.1.1 Commercial Fishery Landings**

460 *Overview of gopher and black-and-yellow catch history*

461 Commercial fishery landings for gopher and black-and-yellow rockfishes have not been re-
462 ported consistently by species throughout the available catch history (Figure 2). The period
463 from 1916-1935 indicates that only black-and-yellow rockfish were landed in the commercial
464 fishery, which then switched to predominately gopher rockfish from 1937-1984. From 1985-
465 1988 the landings data suggest that only black-and-yellow rockfish were landed and not until
466 1995 are both species well-represented in the catches. Pearson et al. (2008) noted:

467 The fact that the majority of estimated landings are not based on actual sam-
468 pling, combined with the likelihood for misidentification [between gopher and
469 black-and-yellow rockfishes], suggests that our landing estimates are generally
470 unreliable [see Figure 37 in Pearson et al. (2008)]. This is particularly true for
471 the time interval between 1983 and 1988. Between 1983 and 1988, market cat-
472 egory 962 (group gopher) landings increased sharply while market category 263
473 (gopher rockfish) landings declined (not visible in Figure 37 since the stratum
474 was unsampled and the landings were converted to unspecified rockfish). Port
475 samples indicated a shift from gopher rockfish to black-and-yellow rockfish during
476 the same time interval, suggesting problems with identification. We suggest that
477 if black-and-yellow landings are combined with gopher landings, the estimates
478 would be generally reliable for the group.

479 There is no way to tease apart the historical catches by species and even across north and
480 south of Point Conception prior to about 1995. This precludes the ability to model the catch
481 histories for either species accurately. Given these constraints, all commercial data were
482 combined to represent one commercial fleet in the assessment. Additional details regarding
483 this decision are described below.

484 The stock assessment of gopher rockfish in 2005 did not include black-and-yellow rockfish
485 landings. A comparison of the recreational and commercial landings from the 2005 assess-
486 ment to those used in this assessment suggest the 2005 assessment may have included some
487 black-and-yellow rockfish landings (Figure 6). The 2005 assessment estimated recreational
488 landings from 1969-1980 based on a ratio of commercial to recreational landings, whereas
489 this assessment makes use of the California Catch Reconstruction landings estimates (Ral-
490 ston et al. 2010).

491 *Commercial Landings Data Sources*

492 The California Catch Reconstruction (Ralston et al. 2010) contains landings estimates of
493 commercial landings from 1916-1968 and was queried on 4 April 2019 for GBYR. There were
494 no estimated gopher rockfish landings prior to 1937. Landings in this database are divided

495 into trawl and ‘non-trawl.’ Since the majority of GBYR are caught in the commercial fixed
496 gear fisheries, only estimated catch in the ‘non-trawl’ was used. A total of 0.154 mt (3.18%)
497 were removed from Eureka commercial landings (based on current proportions of commercial
498 catch from north of Cape Mendocino in Eureka) since the assessment represents the GBYR
499 stock south of Cape Mendocino. The majority of GBYR commercial landings (avg. 83%)
500 are landed in the Monterey and Morro Bay port complexes.

501 Contemporary landings were extracted from two data sources, the California Cooperative
502 Groundfish Survey, [CALCOM](#)) and the Pacific Fisheries Information Network ([PacFIN](#))
503 landings database. Both databases are based on the same data sources (CALCOM landing
504 receipts), but apply a catch expansion based on different algorithms. CALCOM collects
505 information including species composition data (i.e. the proportion of species landed in a
506 sampling stratum), and landing receipts (sometimes called “fish tickets”) that are a record
507 of pounds landed in a given stratum. Strata in California are defined by market category,
508 year, quarter, gear group, port complex, and disposition (live or dead). Although many
509 market categories are named after actual species, catch in a given market category can
510 consist of several species. These data form the basis for the “expanded” landings, i.e.,
511 species composition data collected by port samplers were used to allocate pounds recorded
512 on landing receipts to species starting in 1978. Use of the “Gopher Rockfish” or the “Black-
513 and-Yellow Rockfish” categories alone to represent actual landings of GBY would not be
514 accurate.

515 See Pearson et al. Appendix C ([2008](#)) for a simple example of the expansion calculations
516 for the CALCOM database and a description of the landings in PacFIN can be found in
517 Sampson and Crone ([1997](#)). Both databases, including species compositions, and expanded
518 landings estimates are stored at the Pacific States Marine Fisheries Commission, a central
519 repository of commercial landings data for the U.S. West Coast. As a note, CALCOM is the
520 only source for landings from 1969-1980.

521 Commercial landings from 1981-2018 were queried for a final time from the CALCOM
522 database on 4 April 2019 and from PacFIN on 3 June 2019. There are very small dif-
523 ferences in commercial landings between CALCOM and PacFIN from 1981-2018 (Figure 7).
524 Landings estimates from PacFIN were used in the assessment (Table 1). Landings were
525 stratified by year, quarter, live/dead, market category, gear group, port complex, and source
526 of species composition data (actual port samples, borrowed samples, or assumed nominal
527 market category). Data from individual quarters were aggregated at the year level. Fish
528 landed live or dead were combined, due to changes over time in the reliability of condi-
529 tion information (Don Pearson, retired NMFS SWFSC, personal communication). From
530 1916-1968, on average, 74% of GBYR were landed north of Point Conception, which rose to
531 97% from 1978-2018. Given the smaller landings south of Point Conception and the similar
532 length composition of GBYR north and south of Point Conception, no spatial separation
533 was considered for the commercial fleet.

534 **2.1.2 Commercial Discards**

535 The West Coast Groundfish Observer Program (WCGOP) provides observer data on dis-
536 carding across fishery sectors back to 2003. Gopher and black-and-yellow rockfishes have
537 species-specific depth-stratified commercial fishery discard mortality rates (Pacific Fishery
538 Management Council 2018). In consultation with WCGOP staff, the STAT used estimates of
539 total discard mortality from WCGOP's Groundfish Expanded Mortality Multiyear (GEMM)
540 report. WCGOP observes between 1-5% of nearshore fixed gear landings annually south of
541 40°10' N. latitude (coverage rates available [here](#)). The expanded estimates of total discard
542 weight by species is calculated as the ratio of the observed discard weight of the individual
543 species divided by the observed landed weight from PacFIN landing receipts. WCGOP disc-
544 card estimates for the nearshore fixed gear fishery take into account the depth distribution
545 of landings in order to appropriately apply the depth-stratified discard mortality rates by
546 species (Somers et al. 2018). The discard mortality for 2018 was estimated as an average
547 of the discard mortality from 2013-2017. Discard mortality was estimated from the period
548 prior to WCGOP discard estimates (1916-2002) based on the average discard mortality rate
549 from 2003-2016 (2017 was excluded because 2017 discard mortality was disproportionately
550 higher than all other years) (Table 1).

551 **2.1.3 Commercial Fishery Length and Age Data**

552 Biological data from the commercial fisheries that caught GBYR were extracted from CAL-
553 COM on 9 May 2019. The CALCOM length composition data were catch-weighted to
554 “expanded” length the raw length composition data (Table 2). The 2005 assessment used
555 commercial length composition information from CALCOM, but did not include black-and-
556 yellow rockfish and is not directly comparable. The 2005 assessment used 2 cm length bins
557 from 16-40 cm, where this assessment uses 1 cm length bins from 4-40 cm. Sex was not
558 available for the majority (99.5%) of the commercial length, and the assessment did not
559 find sexual dimorphism in growth for either species. We aggregated the commercial length
560 composition among all gears and regions south of Cape Mendocino.

561 Discard length compositions from WCGOP (2003-2017) were expanded based on the the
562 discard estimates and were aggregated for all regions south of Cape Mendocino and across
563 all fixed gear fisheries.

564 A total of 46 ages were available for gopher rockfish from the commercial fisheries 2009-2011,
565 2016, and 2018. Though sparse, the data were included as conditional age-at-length for the
566 commercial fleet.

567 The input sample sizes for commercial length composition data were calculated via the
568 Stewart Method for fisheries (Ian Stewart, personal communication, IPHC):

569
$$\text{Input effN} = N_{\text{trips}} + 0.138 * N_{\text{fish}} \text{ if } N_{\text{fish}} / N_{\text{trips}} < 44$$

570 Input effN = $7.06 * N_{\text{trips}}$ if $N_{\text{fish}}/N_{\text{trips}}$ is ≥ 44

571 Commercial length composition data are made available from PacFIN and the expanded
572 catch-weight length compositions were provided by Andi Stephens (NWFSC) processed
573 through the [PacFIN Utilities](#) package. We compared differences between the catch-weighted
574 length composition expansions from CALCOM and PacFIN. We were unable to reconcile the
575 difference between the two data sets. Sample sizes became more similar if the PacFIN data
576 were restricted to the same market categories used by CALCOM in the expansion. However,
577 both data sets apply other filters that we did not have time to explore. For instance, in the
578 year 2000, 290 more fish were used in the CALCOM expansion than in PacFIN, but in 2002,
579 150 more fish were used in the PacFIN expansions that were not used in CALCOM. Given
580 these caveats, Figure 8 shows the percent difference in the expanded length comps within a
581 year. The biggest difference is in length bin 32 in 2006. However, the same number of fish
582 and samples were used to expand the 2006 lengths in both databases, indicating there are
583 also fundamental differences in how the data are treated. Full documentation is not available
584 for the PacFIN length composition expansion program. Consequently the STAT chose to use
585 a query that they could completely understand and selectively develop from the CALCOM
586 database for the base model, although a sensitivity was conducted using the PacFIN-derived
587 length composition data.

588 **2.1.4 Recreational Fishery Landings and Discards**

589 *Historical recreational landings and discard, 1928-1980*

590 Ralston et al. ([2010](#)) reconstructed estimates of recreational rockfish catch and discard in
591 California, 1928-1980. Reported landings of total rockfish were allocated to species based
592 on several sources of species composition data. Estimates of GBYR landings and discard
593 (combined) from 1928-1979 are available from the SWFSC. For this assessment, historical
594 recreational catch was stratified by year and area (north and south of Point Conception).
595 The catches of GBYR reported in Ralston et al. ([2010](#)) are higher by an order of magnitude
596 than expected given the more recent catches of GBYR in the MRFSS and CRFS eras south
597 of Point Conception (Figure 9). The recreational catches estimated by Ralston et al. ([2010](#))
598 were discussed with the paper's co-authors and also Commercial Passenger Fishing Vessel
599 (CPFV), i.e., party/charter mode, captains in California. A consensus was reached that
600 the estimated landings did not accurately represent the historical GBYR landings and an
601 alternative catch stream should be developed. One possibility for the inflated catches of
602 GBYR in southern California is that all nearshore shallow species were combined and all
603 of the nearshore deep species were combined and a constant relative fraction between the
604 two was used to assign catches to each combination of CDFW fishing block and year. The
605 fraction of GBYR within the nearshore shallow species group was likely overestimated.

606 The California Catch Reconstruction applied a linear ramp from 1928-1936 that was
607 not altered in this assessment. From 1937-1979 a linear ramp was developed from the

608 1936 estimate to the average recreational landing from 1980 and 1983 (1981-1982 catches
609 interpolated as described in the next section) of 4.3 mt. The recreational catches north of
610 Point Conception were not altered from the original catch reconstruction. The resulting
611 alternate recreational catch streams are in (Table 3 and Figure 10).

612 *Marine Recreational Fisheries Statistics Survey (MRFSS), 1980-2003*

613 From 1980-2003, the Marine Recreational Fisheries Statistics Survey (MRFSS) executed a
614 dockside (angler intercept) sampling program in Washington, Oregon, and California (see
615 Holliday et al. (1984) for a description of methods). Data from this survey are available from
616 the Recreational Fisheries Information Network [RecFIN](#). RecFIN serves as a repository for
617 recreational fishery data for California, Oregon, and Washington. Catch estimates for years
618 1980-2003 were downloaded on 23 March 2019, and are consistent from 1992-2004 with the
619 previous assessment (Key et al. 2005) (Figure 6).

620 MRFSS-era recreational removals for California were estimated for two regions: north and
621 south of Point Conception. No finer-scale estimates of landings are available for this period.
622 Catches were downloaded in numbers and weight. Catch in weight is sometimes missing
623 from the database due to missing average weight estimates. We estimated average weights
624 based on adjacent strata as needed, although the effect was relatively minor (7.4 mt over all
625 years for gopher rockfish and 0.6 mt for black-and-yellow rockfish). Data were not available
626 for the CPFVs in Northern California from 1980-1982, and we used the average value from
627 this mode and region from 1983-1987 for these three years. MRFSS sampling was temporar-
628 ily suspended from 1990-1992, and we used linear interpolation to fill the missing years.
629 Sampling of CPFVs in Northern California was further delayed, and the linear interpolation
630 spans the period 1990-1995 for this boat mode and region. Landings data for the shore-
631 based modes (beach/bank, man-made/jetty and shore) were sparse throughout the MRFSS
632 sampling. All three shore-based modes were combined by region and linear interpolations
633 were applied missing data in 1981 for the Northern California and 1995, 1996-2001, and 2004
634 in Southern California.

635 Catches from north of Cape Mendocino were removed based on a CRFS-era average of frac-
636 tion of recreational landings north of Cape Mendocino by mode (3.3% of shore-based, 0.1% of
637 CPFV, and 0.2% of private/rental were removed). From 1980-1989, San Luis Obispo County
638 was sampled as part of Southern California (personal observation from MRFSS Type 3 sam-
639 pler examined catch where county is available for 1980-2004). This assessment separates the
640 recreational fleet at Point Conception. Recreational landings were re-allocated from southern
641 California from 1980-1992 by fleet based on the average proportion of recreational landings
642 in northern California from 1996-2004 (after sampling of the CPFV fleet in northern Cali-
643 fornia resumed). The average proportion re-allocated from southern to northern California
644 for the CPFV mode was 85%, 97% for the private/rental mode, and 81% for the shore-based
645 modes. Data were pooled over all years and modes to estimate the landings re-allocation
646 for the shore-based modes. Total recreational landings for 1981 and 1982 were 18.8 mt and
647 18.6 mt, respectively. These landings were >60 mt lower than any of the neighboring years.
648 Landings from 1981-1982 were interpolated from the 1980 and 1983 landings.

649 *California Recreational Fisheries Survey (CRFS), 2004-2016*

650 MRFSS was replaced with the California Recreational Fisheries Survey (CRFS) beginning
651 January 1, 2004. Among other improvements to MRFSS, CRFS provides higher sampling
652 intensity, finer spatial resolution (6 districts vs. 2 regions), and onboard CPFV sampling.
653 Estimates of catch from 2004-2018 were downloaded from the RecFIN database a final time
654 on 4 June 2019, We queried and aggregated CRFS data to match the structure of the MRFSS
655 data, by year, and region (Table 3). Catches in the shore-based modes are small compared
656 to the CPFV and private rental modes. All modes are combined, but separated at Point
657 Conception for two recreational fleets in this assessment, just as was done for the California
658 Catch Reconstruction and MRFSS time series.

659 *Recreational Discards*

660 Recreational discards were only added to the California Catch Reconstruction landings, as
661 Ralston et al. (2010) did not address discards for the recreational reconstruction. Recre-
662 ational removals from the California Department of Fish and Wildlife MRFSS era (1980-
663 2003) includes catch type A + B1. Catch type A refers to estimates of catch based on
664 sampler-examined catch. Catch type B1 includes mainly angler-reported discard, but also
665 angler-reported retained fish that were unavailable to the sampler during the interview (e.g.,
666 fillets). The CRFS era removals account for depth-stratified discard mortality rate and the
667 catch time series includes both retained and discarded catch (total mortality). We calculated
668 the ratio of dead discards to total mortality from the CRFS era by region and mode. The
669 region average across modes was applied to the California Catch Reconstruction as a con-
670 stant. The result added 4.68% annually to recreational removals north of Point Conception
671 and 4.05% annually to the removals South of Point Conception). The final time series of
672 landings and discard mortality are in Table 3.

673 **2.1.5 Recreational Fishery Length and Age Data**

674 Recreational length composition samples for California were obtained from several sources,
675 depending on the time period and boat mode (Table 2). This assessment makes use of a
676 much longer time series of length composition data, relative to the previous assessment, as
677 described below. Input sample sizes for recreational length composition data were based on
678 the number of observed trips, when available. Other proxies that were used to estimate the
679 number of trips are described below.

680 There were no standardized coastwide surveys measure retained or discarded fish from the
681 recreational fleet prior to 1980.

682 *CPFV length composition data, 1959-1978*

683 The earliest available length data for this assessment were described by Karpov et al. (1995),
684 who assembled a time series (1959-1972) of available California CPFV length data (made

available courtesy of W. Van Buskirk). For GBYR, data from 1959-1961 and 1966 were available north of Point Conception and from 1959-1961 from south of Pt Conception. A total of 716 (680 north of Point Conception) unsexed measurements of retained fish (no discards) were included in the assessment (Table 2). Sampling of these length data did not follow a consistent protocol over time and areas (data are unweighted), and therefore may not be representative of total catch. Since the number of trips sampled was not reported by Karpov et al. (1995), we assume the number of sampled trips is proportional to the number of measured fish in each year, and estimated the number of trips using the ratio of fish measured per trip in the MRFSS data (roughly 10 fish per trip).

Collins and Crooke (n.d.) conducted an onboard observer survey of the CPFV fleet in southern California from 1975-1978. A total of 1,308 GBYR lengths were available from the study and were assumed to all be from retained fish. Ally et al. (1991) conducted an onboard observer program of the CPFV fleet from 1985-1987 in southern California. Because MRFSS data were available for this time period as well and represents multiple recreational modes, the Ally et al. (1991) length data were not used in the assessment.

MRFSS Recreational Length Data, 1980-1989 and 1993-2003

Unsexed length data of retained fish were collected by MRFSS dockside samplers and downloaded from the RecFIN website. We identified a subset of lengths that were converted from weight measurements, and these were excluded from the final data set (Table 2). The length measurements from Collins and Crooke (n.d.) from 1975-1978 are assumed to all be from retained fish. As of 2003, the CDFW Onboard Observer program has taken length measurements for discarded fish. The retained catch is measured during the dockside (angler intercept) surveys.

The number of CPFV trips used as initial sample sizes for the MRFSS was based on the number of CPFV trips was determined from the trip-level MRFS CPFV database and the number of private boat trips was determined based on unique combinations of the variables ASSNID ,ID_CODE, MODE_FX, AREA_X, DIST, INTSITE, HRSF, CNTRBTRS, SUB_REG, WAVE, YEAR, and CNTY in the Type 3 (sampler-examined catch) data.

During the recent restructuring of the CRFS data on RecFIN, a “trip” identifier was not carried over for all modes, and trip-level sample sizes could not be extracted from the biological detail table on RecFIN. A proxy for initial sample sizes for 2004-2018 were developed using the 2015 data for which I had access to raw data files by mode from CDFW. In more recent years, sampling of the shore-based modes has declined and were not sampled at all in 2018. Samples sizes were calculated by mode as the number of port-days (or site-days for shore-based modes) during bi-weekly intervals (e.g., Jan 1-15, Jan 16-31, etc). The number of port-days sampled in the bi-weekly intervals was used as the initial sample size for number of trips to calculate initial input sample sizes using Ian Stewart’s method (described above). All length data were re-weighted in the assessment model.

723 **2.1.6 Fishery-Dependent Indices of Abundance**

724 A summary of all indices in the assessment can be found in Table 5. Figure 11 shows each
725 index scaled to the mean value of that index to show them all on the same scale, i.e., the
726 mean of each index in the plot is 1.

727 **MRFSS Dockside CPFV Index**

728 From 1980 to 2003 the MRFSS program conducted dockside intercept surveys of recreational
729 fishing fleet. The program was temporarily suspended from 1990-1992 due to lack of fund-
730 ing. For purposes of this assessment, the MRFSS time series was truncated at 1998 due to
731 sampling overlap with the onboard observer program (i.e., the same observer samples the
732 catch while onboard the vessel and also conducts the dockside intercept survey for the same
733 vessel). Each entry in the RecFIN Type 3 database corresponds to a single fish examined
734 by a sampler at a particular survey site. Since only a subset of the catch may be sampled,
735 each record also identifies the total number of that species possessed by the group of anglers
736 being interviewed. The number of anglers and the hours fished are also recorded. The data,
737 as they exist in RecFIN, do not indicate which records belong to the same boat trip. A
738 description of the algorithms and process used to aggregate the RecFIN records to the trip
739 level is outlined Supplemental Materials (“Identifying Trips in RecFIN”).

740 Initial trip filters included eliminating trips targeting species caught near the surface waters
741 for all or part of the trip, including trips with catch of bluefin tuna, yellowfin tuna, skipjack,
742 and albacore.

743 The following filtering steps were applied to gopher rockfish, as well as the sum of the
744 two species to represent GBYR. No filtering or indices were developed for black-and-yellow
745 rockfish alone due to the sparseness in the data. In the raw data, unfiltered data, black-
746 and-yellow rockfish only occurred in 48 trips that did not also observe gopher rockfish.
747 There were an additional 65 trips that encountered both species. There was little difference
748 between indices developed for gopher-only and the GBYR complex for both north and south
749 of Point Conception (Figure 12). The descriptions of the filtering and data below represent
750 those for the GBYR complex.

751 The species composition of catch in California varies greatly with latitude.
752 Therefore, Stephens-MacCall filtering was applied independently for north and south of Point
753 Conception. Separate indices were also developed to represent two recreational fleets in the
754 model. Since recreational fishing trips target a wide variety of species, standardization of
755 the catch rates requires selecting trips that are likely to have fished in habitats containing
756 GBYR. The Stephens-MacCall (2004) filtering approach was used to identify trips with a
757 high probability of catching GBYR, based on the species composition of the catch in a given
758 trip. Prior to applying the Stephens-MacCall filter, we identified potentially informative
759 predictor species, i.e., species with sufficient sample sizes and temporal coverage (at least 30
760 positive trips total) to inform the binomial model. Coefficients from the Stephens-MacCall
761 analysis (a binomial GLM) are positive for species which co-occur with GBYR, and negative

762 for species that are not caught with GBYR. Each of these filtering steps and the resulting
763 number of trips remaining in the sampling frame are provided in Table 16.

764 *MRFSS Filtering and Index Standardization for North of Point Conception.* Prior to the
765 Stephens-MacCall filter, a total of 2,788 trips were retained for the analysis. As expected,
766 positive indicators of GBYR trips include several species of nearshore rockfish, treefish, kelp
767 rockfish, and blue rockfish, and the strongest counter-indicator was striped bass (Figure
768 13). While the filter is useful in identifying co-occurring or non-occurring species assuming
769 all effort was exerted in pursuit of a single target, the targeting of more than one target
770 species can result in co-occurrence of species in the catch that do not truly co-occur in
771 terms of habitat associations informative for an index of abundance. Stpehens and MacCall
772 (Stephens and MacCall 2004) recommended including all trips above a threshold where the
773 false negatives and false positives are equally balanced. However, this does not have any
774 biological relevance and for this data set, we assume that if a GBYR was landed, the anglers
775 had to have fished in appropriate habitat, especially given how territorial GBYR and both
776 species are strongly associated with rocky habitat.

777 Two levels of possible filtering were applied using the Stephens-MacCall filter (Table 16).
778 The Stephens-MacCall filtering method identified the probability of occurrence (in this case
779 0.4) at which the rate of “false positives” equals “false negatives.” The trips selected using
780 this criteria were compared to an alternative method including all the “false positive” trips,
781 regardless of the probability of encountering GBYR (Table 19). This assumes that if GBYR
782 were caught, the anglers must have fished in appropriate habitat during the trip. The catch
783 included in this index is “sampler-examined” and the samplers are well trained in species
784 identification. The last filter applied was to exclude years after 1999 due to a number of
785 regulation changes, and years in which there were less than 20 observed trips. The final
786 index is represented by 544 trips, 220 of which encountered GBYR.

787 Due to the large number of zeros in the data, we modeled catch per angler hour (CPUE;
788 number of fish per angler hour) using maximum likelihood and Bayesian negative binomial
789 regression. Models incorporating temporal (year, 2-month waves) and geographic (region
790 and area_x) factors were evaluated. Counties were grouped into three regions, north of
791 Sonoma county, Sonoma county through Santa Cruz county, and San Luis Obispo county.
792 Based on AIC values from maximum likelihood fits (Table 17), a main effects model including
793 all factors (year, region, area_x, and 2-month waves) was fit in the “rstanarm” R package
794 (version 2.18.2). Diagnostic checks of the Bayesian model fit (Neff, Rhat, and Monte Carlo
795 standard error values) were all reasonable. Predicted means by stratum (Year) were strongly
796 correlated with observed means, suggesting a reasonable fit to the data (Figure 15). The
797 NB model generated data sets with roughly 50-70% zeros, compared to the observed 60%
798 (Figure 16).

799 The index represents the years 1984-1989, 1995, 1996 and 1999. There is not a lot of contrast
800 in the index, except for a small increase in 1986. The final index values and associated log
801 standard error included in the assessment can be found in Table 6.

802 *MRFSS Filtering and Index Standardization for South of Point Conception.* Prior to the

803 Stephens-MacCall filter, a total of 7,334 trips were available for the analysis. As expected,
804 positive indicators of GBYR trips included several nearshore species, e.g., kelp rockfish,
805 treefish, and black croaker, while the strongest counter-indicator was opaleye (Figure 17).
806 While the filter is useful in identifying co-occurring or non-occurring species assuming all
807 effort was exerted in pursuit of a single target, the targeting of more than one target species
808 can result in co-occurrence of species in the catch that do not truly co-occur in terms of
809 habitat associations informative for an index of abundance. For consistency with the methods
810 used north of Point Conception (Table 16) the index includes the trips identified as “false
811 positives” from the Stephens-MacCall filtering that had a lower threshold level of 0.22 (Table
812 20). The last filter applied was to exclude years after 1999 due to a number of regulation
813 changes, and years in which there were less than 20 observed trips. The final index is
814 represented by 475 trips, 342 of which encountered GBYR.

815 Catch per angler hour (CPUE; number of fish per angler hour) was modelled using the delta-
816 GLM approach (Lo et al. 1992, Stefánsson 1996). A negative binomial model was explored,
817 but the proportion of zeroes was not well estimated in the negative binomial models. This
818 is likely due to the facts that MRFSS sampling effort was higher south of Point Conception,
819 and GBYR are also rare south of Point Conception, both leading to a higher proportion of
820 zeroes in the trip data than for north of Point Conception.

821 Model selection using Akaike Information Criterion (AIC) supported inclusion of year, region,
822 area_x, and 2-month waves. Counties were grouped into three regions, Santa Barbara to
823 Ventura counties, Los Angeles and Orange counties, and San Diego county for both the
824 positive observation model and the binomial model. Area_x is a measure of distance from
825 shore, a categorical variable indicating whether most of the fishing occurred inside or outside
826 three nautical miles from shore.

827 The resulting index for south of Point Conception represents different years than the index for
828 north of Point Conception (Table 6). The index starts in 1980 with continuous data through
829 1986, and three additional years in 1996, 1998 and 1999. The index increases through 1983
830 and a marked decrease to 1986. The index for the three years in the 1990s does not exhibit
831 any significant trend.

832 **CPFV Onboard Observer Surveys**

833 Onboard observer survey data were available from three sources for this assessment, 1)
834 a CDFW survey in central California from 1987-1998 (referred to as the Deb Wilson-
835 Vandenberg onboard observer survey, (Reilly et al. 1998)), 2) the CDFW CPFV onboard
836 observer survey from 1999-2018, and 3) a Cal Poly survey from 2003-2018. During an on-
837 board observer trip the sampler rides along on the CPFV and records location-specific catch
838 and discard information to the species level for a subset of anglers onboard the vessel. The
839 subset of observed anglers is usually a maximum of 15 people the observed anglers change
840 during each fishing stop. The catch cannot be linked to an individual, but rather to a specific
841 fishing location. The sampler also records the starting and ending time, number of anglers
842 observed, starting and ending depth, and measures discarded fish.

843 The fine-scale catch and effort data allow us to better filter the data for indices to fishing
844 stops within suitable habitat for the target species.

845 The state of California implemented a statewide sampling program in 1999 (Monk et al.
846 2014). California Polytechnic State University (Cal Poly) has conducted an independent
847 onboard sampling program as of 2003 for boats in Port San Luis and Morro Bay, and follows
848 the protocols established in Reilly et al. (1998). Cal Poly has modified protocols reflect
849 sampling changes that CDFW has also adopted, e.g., observing fish as they are encountered
850 instead of at the level of a fisher's bag. Therefore, the Cal Poly data area incorporated in
851 the same index as the CDFW data from 1999-2018. The only difference is that Cal Poly
852 measures the length of both retained and discarded fish.

853 We generated separate relative indices of abundance in for the 1987-1999 and 2000-2018
854 data sets due to the number of regulation changes occurring throughout the time period (see
855 Appendix B). Separate indices were also developed for north and south of Point Conception.

856 *Deb Wilson-Vandenberg Onboard Observer Index Filtering and Standardization.* A large
857 effort was made by the SWFSC to recover data from the the original data sheets for this
858 survey and developed into a relational database (Monk et al. 2016). The specific fishing
859 locations at each fishing stop were recorded at a finer scale than the catch data for this survey.
860 We aggregated the relevant location information (time and number of observed anglers) to
861 match the available catch information. Between April 1987 and July 1992 the number of
862 observed anglers was not recorded for each fishing stop, but the number of anglers aboard the
863 vessel is available. We imputed the number of observed anglers using the number of anglers
864 aboard the vessel and the number of observed anglers at each fishing stop from the August
865 1992-December 1998 data (see Supplemental materials for details). In 1987, trips were only
866 observed in Monterey, CA and were therefore excluded from the analysis. The years 1990
867 and 1991 were also removed for low sample sizes. Final data filters included removing reefs
868 that never encountered GBYR, drifts that had fishing times outside 95% of the data, and
869 fishing stops with depths <9 m and >69m. The final data set contained 2,411 fishing stops,
870 with 1,096 of those encountering GBYR (Figure 18).

871 The index was fit using a delta-GLM model, with a lognormal model (AIC: 1,088) selected
872 over a gamma model (AIC: 1,143) for the positive encounters. Covariates considered in
873 the full model included year, depth, and month (Table 8). The model selected by AIC for
874 both the lognormal and binomial components of the delta-GLM included year, depth and
875 reef. Depth was included in 10 m depth bins and eight reefs were select in the final model
876 (Figure coming). The final index did not indicate an increasing trend that was seen in the
877 2005 gopher rockfish assessment using the same data set (Figure 19). A number of reasons
878 include that finer-scale location data was keypunched in 2012 for this survey, the index in
879 this assessment includes black-and-yellow rockfish, and different filters were applied to the
880 data. However, the the same peaks and decreases in the two indices are present.

881 *CDFW and Cal Poly Onboard Observer Index Filtering and Standardization* As described
882 above the CDFW and Cal Poly onboard observer programs are identical in that the same

883 protocols are followed. The only difference is that Cal Poly measures both retained and
884 discarded fish from the observed anglers. CDFW measures discarded fish only from the
885 observed anglers, and measures retained fish as part of the angler interview at the bag level.
886 Cal Poly has also begun collecting otoliths during the onboard observer trips, which are used
887 as conditional age-at-length data the recreational fishery north of Point Conception in this
888 assessment.

889 A number of filters are applied to these data. All of the Cal Poly data have been through
890 a QA/QC process once key-punched, whereas a number of errors remain in the data from
891 CDFW. Data sheets from CDFW are not longer available prior to 2012 and staff constraints
892 have also prevented a quality control review of the data.

893 Each drift was assigned to a reef (hard bottom). Hard bottom was extracted from the
894 [California Seafloor Mapping Project](#), with bathymetric data from state waters available at
895 a 2 m resolution. Reefs were developed based on a number of factors described in the
896 supplemental material (“Reef Delineation”).

897 Initial filters were applied to the entire data set, north and south of Point Conception com-
898 bined. After an initial clean-up of the data, 67,850 drifts remained, with GBYR present
899 in 9,317 (Table 9). This was reduced to 25,427 drifts with GBYR present in 7,250 drifts
900 after filtering the data to remove potential outliers in the time fished and observed anglers,
901 limiting the data to reefs that observed GBYR and were sampled in at least 2/3 of all years,
902 and to drifts with starting locations within 1,000 m of a reef.

903 Recreational fishing trips north and south of Point Conception can be fundamentally different
904 due to differences in habitat structure, target species, and weather.

905 *Filtering and Index Standardization for north of Point Conception* The number of drifts
906 remaining before region specific filtering was 13,792, with 6,036 drifts encountering GBYR
907 (Table 9).

908 Because GBYR are strongly associated with hard bottom habitat, the distance from a reef at
909 the start of a drift was re-examined for drifts encountering GBYR. The maximum distance
910 was 872 m, but the 97% quantile dropped to 42 m and was chosen as a reasonable cutoff
911 value, and only resulted in a reduction of 182 drifts that encountered gopher rockfish. The
912 final data were filtered to ensure all selected reefs were sampled in at least 2/3 of all years,
913 leaving 12,965 drifts for the final index, 5,796 of which encountered GBYR (Figure 20).

914 The index of abundance was modeled with a delta-GLM modeling approach, with year,
915 month, 10 m depth bins from 10-59 m, and 12 reefs as possible covariates. A lognormal
916 model (AIC: 12,185) was selected over a gamma (AIC: 12,520) for the positive observations
917 using AIC. The full model was selected by AIC for the lognormal and binomial components
918 of the delta-GLM. The index indicates a relatively stable trend from 2001-2009 and a steady
919 decrease from 2010-2013. The relative index of abundance has increased since 2014.

920 *Filtering and Index Standardization for south of Point Conception* The bathymetric data is
921 not available at as fine-scale resolution for the Southern California Bight and more of the

922 trips and drifts target mid-water species, including mid-water rockfish (Table 9). Therefore,
923 instead of using distance to reef as a filter, we filtered the data to drifts that encountered
924 20% or more groundfish. This resulted in the total number of drifts decreasing from 11,635
925 to 5,495, but only decreased the number of drifts encountering GBYR from 1,277 to 1,171.
926 A final check was made to ensure all reefs were sampled in at least 2/3 of all years, leaving
927 5,440 drift for the final index, of which 1,132 encountered GBYR (Figure 21).

928 The index of abundance was modeled with the a delta-GLM modeling approach, with year,
929 month, 10 m depth bins from 10-59 m, and four reefs as possible covariates. A lognormal
930 model (AIC: 162) was selected over a gamma (AIC: 277) for the positive observations using
931 AIC. A model with year, depth and reef was selected by AIC for both the lognormal and
932 binomial components of the delta-GLM. The index indicates a relatively stable trend from
933 2001-2004 and a steady increase from 2005-2017.

934 2.1.7 Fishery-Dependent Indices: Available Length and Age Data

935 Length data associated with the MRFSS dockside CPFV survey and the current onboard ob-
936 server surveys conducted by CDFW are incorporated into the biological data pulled from the
937 respective data sources, MRFSS and CRFS. The additional length data are not incorporated
938 as separate length composition data as they represent the same portion of the population
939 sampled by the CDFW onboard observer program.

940 Cal Poly collected otoliths from the onboard observer program starting in 2017 as part of
941 a special study to correlate fish length before and after the fish was filleted by the
942 deckhands onboard the CPFV vessels. All fish collected in 2017 only had associated post-
943 fillet lengths and were not used in the assessment since the study has not been finalized nor
944 has the method been endorsed by the SSC. A subset of fish from the 2018 collection included
945 both pre- and post-fillet length and were used in the assessment as conditional age-at-length
946 data associated with the recreational fleet north of Point Conception.

947 Length composition from Deb Wilson-Vandenberg's onboard observer survey are included
948 in the assessment. This program measured both retained and discarded fish, and represent
949 the portion of the population sampled with the spatial extent of the index. This onboard
950 observer program continued during the period from 1990-1992 when MRFSS was on hiatus.

951 2.1.8 Fishery-Independent Data Sources

952 Neither of the two fishery-independent surveys described below have previously been used
953 in stock assessments as indices of abundance.

954 California Collaborative Fisheries Research Project

955 The California Collaborative Fisheries Research Project, CCFRP, is a fishery-independent
956 hook-and-line survey designed to monitor nearshore fish populations at a series of sampling
957 locations both inside and adjacent to MPAs along the central California coast (Wendt and
958 Starr 2009, Starr et al. 2015). The CCFRP survey began in 2007 and was originally designed
959 as a statewide program in collaboration with NMFS scientists and fishermen. From 2007-
960 2016 the CCFRP project was focused on the central California coast, and has monitored four
961 MPAs consistently since then (Figure 22). In 2017, the program was expanded coastwide
962 within California. The index of abundance was developed from the four MPAs sampled
963 consistently (Año Nuevo and Point Lobos by Moss Landing Marine Labs; Point Buchon and
964 Piedras Blancas by Cal Poly).

965 The survey design for CCFRP consists a number 500 x 500 m cells both within and outside
966 each MPA. On any given survey day for a chose site cells are randomly selected within a
967 stratum (MPA and/or reference cells). CPFVs are chartered for the survey and the fishing
968 captain is allowed to search within the cell for a fishing location. During a sampling event,
969 each cell is fished for a total of 30-45 minutes by volunteer anglers. Each fish encountered is
970 recorded, measured, and can be linked back to a particular angler, and released (or descended
971 to depth). Starting in 2017, a subset of fish have been retained to collect otoliths and fin clips,
972 needed biological information for nearshore species. For the index of abundance, CPUE was
973 modelled at the level of the drift, similar to the fishery-dependent onboard observer survey
974 described above.

975 The CCFRP data are quality controlled at the time they are key punched and little filtering
976 was needed for the index. Cells not consistently sampled over time were excluded as well as
977 cells that never encountered GBYR. CCFRP samples shallower depths to avoid barotrauma-
978 induced mortality. The index was constrained to 5-39m in 5 m depth bins. The final index
979 included 4,920 drifts, 3,848 of which encountered GBYR.

980 We modeled catch per angler hour (CPUE; number of fish per angler hour) using maximum
981 likelihood and Bayesian negative binomial regression. The proportion of zeroes in this data
982 was relatively small (22%), and if overdispersion were not present, the regression would
983 innately become Poisson. Models incorporating temporal (year, month) and geographic
984 (MPA site and MPA vs Reference cells) factors were evaluated. Based on AIC values from
985 maximum likelihood fits (Table 15), a main effects model including all factors (year, month,
986 site and MPA/REF) was fit in the “rstanarm” R package (version 2.18.2). Diagnostic checks
987 of the Bayesian model fit (Neff, Rhat, and Monte Carlo standard error values) were all
988 reasonable. Predicted means by stratum (Year) were strongly correlated with observed
989 means, suggesting a reasonable fit to the data (Figure 23). The NB model generated data
990 sets with roughly 18-22% zeros, compared to the observed 22% (Figure 16).

991 The CCFRP index of abundance closely matches the trend observers in the onboard observer
992 index from 2009-2018 (Figure 11). The index decreases from 2009 to 2013, and then exhibits
993 the same increase through 2018. When both indices are standardized to their means, the
994 values for 2013 and 2018 are the same.

995 *CCFRP Length Measurements and Available Ages*

996 The CCFRP program measures every fish encountered to the nearest half centimeter. A
997 total of 22,470 GBYR were measured by CCFRP from 2007-2018, of which only 212 were
998 black-and-yellow rockfish. The length distributions for each of the four MPAs used in the
999 index for this assessment show slight difference in their peaks (Figure 25). Año Nuevo is the
1000 most northern site and Point Buchon the most southern.

1001 Conditional age-at-length data were also incorporated into the assessment from the CCFRP
1002 program, including two master's theses that are products of the CCFRP. Erin Loury (Loury
1003 2011) collected gopher rockfish otoliths as part of her thesis work from 2007-2009 that in-
1004 cluded specimens from both inside and outside the MPAs. Natasha Meyers-Cherry (Meyers-
1005 Cherry 2014) conducted another thesis focused on the life history of gopher rockfish and
1006 collected otoliths from 2011-2012, also both inside and outside the MPAs. Both MLML and
1007 Cal Poly began routinely collecting otoliths from a select number of fish in 2017 as part of
1008 the CCFRP program. Also included in the conditional age-at-length data for this fleet are
1009 otoliths collected in 2018 by the University of California Davis Bodega Marine Lab CCFRP
1010 program.

1011 Partnership for Interdisciplinary Studies of Coastal Oceans

1012 The Partnership for Interdisciplinary Studies of Coastal Oceans, [PISCO-UCSC](#), conducts
1013 a number of surveys to monitor the kelp forests, one of which is a kelp forest fish survey.
1014 PISCO has monitored fish population in the 0-20 m depth range as part of the Marine Life
1015 Protection Act (MLPA) since 1998. Paired sites inside and outside MPAs are surveyed to
1016 monitor the long-term dynamics of the kelp forest ecosystem and provide insight into the
1017 effect of MPAs on kelp forest species. PISCO conducts the fish surveys from late July through
1018 September. At each site, benthic, midwater, and canopy scuba transects are conducted at
1019 5, 10, 15, and 20 m depth. All divers are trained in species identification. Along each 30
1020 m transect, divers enumerate all identifiable non-cryptic fish, and measure total length to
1021 the nearest centimeter. PISCO surveys are conducted by the University of California Santa
1022 Cruz (UCSC) in central California and through the University of California Santa Barbara
1023 in southern California. All PISCO data were provided by Dan Malone (UCSC).

1024 The majority of filtering for the PISCO data set was to determine which sites to keep for
1025 the final index. After initial filtering the data for GBYR in southern California were too
1026 sparse to be considered for the index of abundance. Gopher and black-and-yellow rockfish
1027 were also rarely observed in the midwater and canopy transects, and therefore the index is
1028 based only on the benthic transects. Only sites sampled consistently throughout the time
1029 period 2001-2018 were kept for the index. Multiple transects can be conducted along the
1030 same line within a sampling event. All transects within a site were combined and effort was
1031 modeled as the number of transects represented in the number of fish observed. The final
1032 index included 3,231 transects, of which 1,729 observed GBYR (Figure 26).

1033 We modeled number of fish observed per transect(s) using maximum likelihood and Bayesian
1034 negative binomial regression. Models incorporating temporal (year, month) and geographic
1035 (site and zone) factors were evaluated. The zone is a factor indicating the depth stratification

1036 at a site, i.e., 5 m, 10 m, 15 m, or 20 m targeted bottom depth.. Based on AIC values from
1037 maximum likelihood fits (Table 13), a main effects model including all factors (year, month,
1038 site and zone) was fit in the “rstanarm” R package (version 2.18.2). Diagnostic checks of the
1039 Bayesian model fit (Neff, Rhat, and Monte Carlo standard error values) were all reasonable.
1040 Predicted means by stratum (Year) were strongly correlated with observed means, suggesting
1041 a reasonable fit to the data (Figure 27). The NB model generated data sets with roughly
1042 16-25% zeros, compared to the observed 23% (Figure 28).

1043 The final index decreases from 2001 to the late 2000s, with lower estimates of relative abun-
1044 dance from 2005-2010. From 2010 to 2015, the index increases and peaks in 2015, before
1045 the decreasing trends from 2016-2018. The trend observed in this index is counter to that
1046 observed in the onboard observer and CCFRP indices for north of Point Conception (Fig-
1047 ure 11). The PISCO survey is sampling different habitat types than the other two surveys,
1048 and covers much shallower depths. It’s possible that the PISCO index captures recruitment
1049 pulses, but because this index includes both young-of-the-year and adult fish, the trend may
1050 be captured in the model.

1051 *PISCO Length Measurements*

1052 Every GBYR observed by PISCO divers except one, had an associated length measurement
1053 ($N = 11,965$). Divers measure fish to the nearest centimeter, and are trained to measure fish
1054 underwater and be aware of possible biases, e.g., ambient light, body color, visibility, and
1055 body shape. Both juvenile and adult GBYR were observed in the PISCO kelp forest fish
1056 survey data (Figure 29). Of note is the similarity in length distributions both between the
1057 species and for the two species combined across sites. Fish in the 10-17 cm size range (ap-
1058 proximately) are not observed in this survey. There is significant post-settlement mortality
1059 for both species, which is thought to be due to density-dependent predation (Johnson 2006,
1060 2007). Secondly, both species are cryptic and observed more often at night than during the
1061 day (Mark Carr, PISCO-UCSC, personal communication).

1062 **2.1.9 Biological Parameters and Data**

1063 Neither gopher nor black-and-yellow rockfish have forked tails, therefore total length and
1064 fork length are equal. All of the data provided for this assessment were either in fork length
1065 or total length.

1066 (Table 4)

1067 **Length and Age Compositions**

1068 Length compositions were provided from the following sources:

- 1069 • CALCOM (*commercial retained dead fish*, 1987, 1992-2018)

- WCGOP (*commercial discarded fish*, 2004-2018)
- Deb Wilson-Vandenberg's onboard observer survey (*recreational charter retained and discarded catch*, 1987-1998)
- California recreational sources combined (*recreational charter retained catch*)
 - Miller and Gotshall dockside survey (1959-1966)
 - Ally et al. onboard observer survey (1985-1987)
 - Collins and Crooke onboard observer survey (1975-1978)
 - MRFSS dockside survey (1980-2003)
 - CRFS onboard and dockside survey (2004-2018)
- PISCO dive survey (*research*, 2001-2018)
- CCFRP hook-and-line survey (*research*, 2007-2018)

The length composition of all fisheries aggregated across time by fleet is in Figure 30 and Table 4. Descriptions and details of the length composition data are in the above section for each fleet or survey.

Age Structures

A total of 2,421 otoliths were incorporated in this assessment and a summary by source can be found in Table 21. The final base model excludes the commercial age data that were sparse and not representative of the fishery. Gopher rockfish comprised 79% of the samples (922 females, 879 males, 121 unknown sex), and all but a few black-and-yellow rockfish (247 females, 232 males, 20 unknown sex) came from a directed study by Jody Zaitlin (1986), collected from 1983-1986 (Figure 31).

Of the available ages, 94% were collected during fishery-independent surveys. The remaining 6% were recreational dockside surveys and collected by Cal Poly during their CPFV onboard observer survey (36 otoliths) in 2018.

All otoliths were read by Don Pearson (NMFS SWFSC, now retired) and estimated ages ranged from 1-28. The aged black-and-yellow rockfish ranged in length from 7-32 cm with a mean of 24 cm and gopher rockfish ranged in length from 11-36 cm, with a mean of 26. In terms of ages, the black-and-yellow rockfish ranged from 2-19 and gophers from 2-28. Fits to the von Bertalanffy growth curve (Bertalanffy 1938), $L_i = L_\infty e^{(-k[t-t_0])}$, where L_i is the length (cm) at age i , t is age in years, k is rate of increase in growth, t_0 is the intercept, and L_∞ is the asymptotic length, were explore by species and sex.

No significant differences were found in growth between gopher and black-and-yellow rockfishes (Figure 32) or between males and females (Figure 33), species combined.

Aging Precision and Bias

Uncertainty in ageing error was estimated using a collection of 376 gopher and black-and-yellow rockfish otoliths with two age reads (Figure 35). Age-composition data used in the

¹¹⁰⁶ model were from a number of sources described above. All otoliths were read by Don Pearson
¹¹⁰⁷ (NMFS SWFSC, no retired) who also conducted all blind double reads.

¹¹⁰⁸ Ageing error was estimated using publicly available software (Thorson et al. [2012](#)). The
¹¹⁰⁹ software setting for bias was set to unbiased since the same reader conducted the first and
¹¹¹⁰ second readings. The best fit model chose by AIC for the standard deviation was a constant
¹¹¹¹ coefficient of variation for reader one ad mirrored for reader two (Figure [36](#)).

¹¹¹² The resulting estimate indicated a standard deviation in age readings increasing from 0.74
¹¹¹³ years at age 0 to a standard deviation of 2.07 years at age 28, the first year of the plus group
¹¹¹⁴ in the assessment model.

¹¹¹⁵ Weight-Length

¹¹¹⁶ The weight-length relationship is based on the standard power function: $W = \alpha(L^\beta)$ where
¹¹¹⁷ W is individual weight (kg), L is length (cm), and α and β are coefficients used as constants.

¹¹¹⁸ The weight-length relationships was estimated from the three studies, Loury ([2011](#)), Meyers-
¹¹¹⁹ Cherry ([2014](#)) (both gopher rockfish only from CCFRP) and Zaitlin (Zaitlin [1986](#)) (black-
¹¹²⁰ and-yellow rockfish only). Only one weight-length relationship was estimated for the GBYR
¹¹²¹ complex. The estimated parameters are $\alpha = 8.84e^{-006}$ and $\beta = 3.25584$. The estimated
¹¹²² relationship is similar to that estimated by Lea et al. ([1999](#)) for gopher rockfish (Figure
¹¹²³ [37](#)). The weight-length relationship estimated here was used in the assessment model to
¹¹²⁴ best represent the GBYR complex.

¹¹²⁵ Sex Ratio, Maturity, and Fecundity

¹¹²⁶ The sex ratio for GBYR is assumed to be 50:50 as there is no evidence to suggest otherwise.

¹¹²⁷ Zaitlin ([1986](#)) found that females reached 50% maturity at 17.5 cm or 4 years of age in
¹¹²⁸ Central California and were 100% mature by age 6, with the same age of maturity found
¹¹²⁹ in southern California though individuals were smaller at age. However, all ages from this
¹¹³⁰ study were surface ages and were re-read for this assessment. Echeverria ([1987](#)) estimated
¹¹³¹ maturity for 17 rockfish species in central California. She found the size at first maturity
¹¹³² and the size at 50% maturity for male and female gopher rockfish to be 17 cm total length,
¹¹³³ and 100% mature by 21 cm. Black-and-yellow rockfish males and females were first mature
¹¹³⁴ at 14 cm, 50% of females were mature at 15 cm, 50% of males mature at 16 cm. Male
¹¹³⁵ black-and-yellow rockfish were 100% mature at 20 cm and females at 19 cm. In southern
¹¹³⁶ California waters, both males and females were found to reach first maturity at 13 cm total
¹¹³⁷ length (Larson [1980](#)). We did not have any samples from southern California to re-analyze
¹¹³⁸ the maturity ogive for that portion of the population.

¹¹³⁹ The maturity data from Zaitlin ([1986](#)) (422 black-and-yellow rockfish) were re-analyzed along
¹¹⁴⁰ with samples from Meyers-Cherry ([2014](#)) (115 gopher rockfish). Combining the two data sets

1141 provided an updated maturity ogive for the GBYR complex females (Figure 34). The first
1142 observed mature fish was 19 cm and the length at 50% was 21.66 cm, larger than suggested
1143 from the estimate used by Key et al. (2005) in the 2005 assessment. After re-analyzing the
1144 available data, the length at which 50% of female gopher rockfish were mature was estimated
1145 at 23.33 cm, and was 21.26 cm for female black-and-yellow rockfish. An important note is
1146 that the smaller fish from these studies were black-and-yellow rockfish and the larger fish
1147 were gopher rockfish. Although not used in this assessment, the estimate of 50% maturity
1148 for 23 GBYR from these studies was 21.88 cm. The age at 50% mature increased in this
1149 assessment to 21.66 cm, which is 3.96 cm larger than the value used in the 2005 assessment.

1150 Mature females in central California release larvae between January and July, peaking in
1151 February, March, and May (Larson 1980, Lea et al. 1999, Love et al. 2002). Both species of
1152 GBYR release one brood per season (Love et al. 2002). Black-and-yellow rockfish females
1153 can produce 25,000 - 450,000 eggs spawning from January to May. Gopher rockfish females
1154 ranging between 176 and 307 grams carry approximately 249 eggs per gram of body weight
1155 (MacGregor 1970). The fecundity estimates used in this assessment were provided by E.J.
1156 Dick (NMFS SWFSC) from a meta-analysis of fecundity in the genus *Sebastodes* (Dick et al.
1157 2017).

1158 Natural Mortality

1159 Hamel (2015) developed a method for combining meta-analytic approaches to relating the
1160 natural mortality rate M to other life-history parameters such as longevity, size, growth
1161 rate and reproductive effort, to provide a prior on M . In that same issue of ICESJMS,
1162 Then et al. (2015), provided an updated data set of estimates of M and related life history
1163 parameters across a large number of fish species, from which to develop an M estimator
1164 for fish species in general. They concluded by recommending M estimates be based on
1165 maximum age alone, based on an updated Hoenig non-linear least squares (nls) estimator
1166 $M = 4.899 * A_{max}^{-0.916}$. The approach of basing M priors on maximum age alone was one that
1167 was already being used for west coast rockfish assessments. However, in fitting the alternative
1168 model forms relating $-0.916M$ to A_{max} , Then et al. (2015) did not consistently apply their
1169 transformation. In particular, in real space, one would expect substantial heteroscedasticity
1170 in both the observation and process error associated with the observed relationship of M to
1171 A_{max} . Therefore, it would be reasonable to fit all models under a log transformation. This
1172 was not done. Reevaluating the data used in Then et al. (2015) by fitting the one-parameter
1173 A_{max} model under a log-log transformation (such that the slope is forced to be -1 in the
1174 transformed space (as in Hamel (2015)), the point estimate for M is:

$$M = \frac{5.4}{A_{max}} \quad (1)$$

1175 The above is also the median of the prior. The prior is defined as a lognormal with mean
1176 $\ln \frac{5.4}{A_{max}}$ and SE = 0.4384343 (Owen Hamel, personal communication, NMFS). Using a max-

¹¹⁷⁷ imum age of 28 the point estimate and median of the prior is 0.193, which is used as a prior
¹¹⁷⁸ for in the assessment model.

¹¹⁷⁹ 2.1.10 Environmental or Ecosystem Data Included in the Assessment

¹¹⁸⁰ In this assessment, neither environmental nor ecosystem considerations were explicitly in-
¹¹⁸¹ cluded in the analysis. This is primarily due to a lack of relevant data and results of analyses
¹¹⁸² (conducted elsewhere) that could contribute ecosystem-related quantitative information for
¹¹⁸³ the assessment.

¹¹⁸⁴ 2.2 Previous Assessments

¹¹⁸⁵ 2.2.1 History of Modeling Approaches Used for this Stock

¹¹⁸⁶ This is the first full assessment to include data for black-and-yellow rockfish. Black-and-
¹¹⁸⁷ yellow rockfish was assessed coastwide as a data poor species using Depletion-Based Stock
¹¹⁸⁸ Reduction Analysis (DB-SRA) (Dick and MacCall [2010](#)). The DB-SRA model assigned a
¹¹⁸⁹ 40% probability that the then recent (2008-2009) catch exceeded the 2010 OFL.

¹¹⁹⁰ Gopher rockfish south of Point Conception was assessed as a data poor species in 2010 (Dick
¹¹⁹¹ and MacCall [2010](#)). A Depletion-Corrected Average Catch (DCAC) model was used due to
¹¹⁹² time constraints. The mean yield from the DCAC distribution was 25.5 mt.

¹¹⁹³ Gopher rockfish north of Point Conception ($34^{\circ}27'$ N. latitude) was first assessed a full stock
¹¹⁹⁴ assessment in 2005 (Key et al. [2005](#)) using SS2 (version 1.19). The assessment was sensitive
¹¹⁹⁵ to the CPFV onboard observer index of abundance (referred to as Deb Wilson-Vandenbergs
¹¹⁹⁶ onboard observer index in this assessment). The final decision table was based around the
¹¹⁹⁷ emphasis given to the index, with a value of 5 given a 40% probability and used in the
¹¹⁹⁸ baseline model. The stock was found to be at 97% depletion.

¹¹⁹⁹ 2.2.2 2005 Assessment Recommendations

¹²⁰⁰ The 2005 STAR panel only had one recommendation specific to gopher rockfish. However,
¹²⁰¹ they had a number of generic rockfish recommendations that can be found in the STAR
¹²⁰² panel report available [here](#).

¹²⁰³ **Recommendation 1:** Additional length and age composition data should be
¹²⁰⁴ collected for gopher rockfish. This would help to characterize spatial and

1205 **possibly temporal variation in growth**

1206
1207 2019 STAT response: Additional age and length data have been collected from a num-
1208 ber of sources, the majority of which have been fishery-independent studies, including
1209 two master's theses focused on gopher rockfish. Only a handful of otoliths have been
1210 collected for gopher rockfish south of Point Conception. Additional length composition
1211 data are available since the last assessment.

1212

2.3 Model Description

1213 The mode descriptions in the following sections reflect decisions and modelling choices the
1214 STAT team made prior to the STAR panel. Changes from the pre-STAR base model to the
1215 final post-STAR base model are documented in the "Responses to the Current STAR Panel
1216 Requests" section. None of the data changed during the STAR panel, and the figures and
1217 tables reflect the post-STAR final base model.

1218 While investigating convergence issues in the cowcod assessment, Richard Methot (NMFS)
1219 identified an issue with the performance of the 'sfabs' function in ADMB. This led to poor
1220 convergence during the iterative search for Fspr under certain conditions. Dr. Methot re-
1221 solved the issue, and provided a new 'safe' version of SS (V3.30.13.09) to the cowcod and
1222 GBYR STATs on June 28, followed by an optimized executable on June 30. Apart from the
1223 iterative Fspr search mentioned above, other model outputs and analyses were unaffected
1224 by the change. All of the base model results were run in this newest version of SS

1225

2.3.1 Transition to the Current Stock Assessment

1226 The first formal stock assessment for gopher rockfish was conducted in 2005 (Key et al.
1227 2005). There are two major differences between the 2005 assessment this assessment, 1) this
1228 assessment models gopher and black-and-yellow rockfish as a complex, and 2) this assessment
1229 includes the area south of Point Conception.

1230 The 2005 model conducted in SS2 version 1.19 was first transitioned to SS3.24z as a bridge
1231 model, before moving forward to SS3.30. Below, we describe the most important changes
1232 made since the last full assessment in 2005 and explain rationale for each change. Some of
1233 these items are changes due to structure changes with Stock Synthesis, and some denote
1234 parameters chosen for options that were not available in SS2 (version 1.19).

1235 Changes in the bridge model from SS2 version 1.9 to SS3.24z and SS3.30.13.09 include:

1236 The way growth is modeled for age-0 fish has changed. More recent versions of Stock Syn-
1237 thesis model length-at-age for fish below the first reference age (Amin) as linearly increasing

1238 from the initial length bin to the length given by the L_at_Amin parameter. The mini-
1239 mum population length bin was reduced from 10 cm in the 2005 assessment to 4 cm in this
1240 assessment. The timing of settlement was set at July to reflect the month at which
1241 the young-of-the-year are expected to be at 4 cm (Figure 38). The length data leading to
1242 this decision were provided by Diana Baetscher (UCSC) and were collected via Standard
1243 Monitoring Unit for the Recruitment of Fishes (SMURFs) (Ammann 2004) from the UCSC-
1244 PISCO kelp forest fish survey as part of her dissertation work on rockfish genetics (Baetscher
1245 2019).

1246 This stock assessment retains a single fleet for the commercial fishery, and also includes
1247 a commercial discard fleet. Data on commercial discards were not available for and not
1248 included in the 2005 assessment. The decision to retain one commercial fleet was made by
1249 examining the length distributions across species, fishing gears, and space, i.e., north and
1250 south of Point Conception (Figure 39). There is very little difference between the length
1251 composition of gopher and black-and-yellow rockfish landed in the commercial fleet north of
1252 Point Conception, which contributed 97% of the commercial landings from 1978-2018. The
1253 length distributions suggest that gopher rockfish south of Point Conception landed dead
1254 south of Point Conception are slightly smaller on average than north of Point Conception.
1255 However, there is not enough data available to justify splitting the commercial fishery north
1256 and south of Point Conception. The length compositions of discarded fish are small in all
1257 of the subplots, suggesting size-based discarding. Because Stock Synthesis is not set up to
1258 handle depth-dependent discard mortality rates and we're modelling two species as a complex
1259 with differing depth-dependent discard mortality rates, the time series of commercial discards
1260 was incorporated as a fleet.

1261 This assessment incorporates the area south of Point Conception, which was previously
1262 excluded from the 2005 assessment. The length composition data suggested that while the
1263 lengths of gopher and black-and-yellow rockfish were similar, fish encountered south of Point
1264 Conception were smaller (Figure 40). The recreational catches from the man made mode
1265 are negligible and did not influence the decision to split the fleet at Point Conception. The
1266 similarity of the length distributions between species and among modes within a region were
1267 similar and justified one recreational fleet.

1268 The 2005 model was a length-based model. This assessment uses conditional age-at-length
1269 from fish aged from a number of sources (Table 21).

1270 Differences in both the recreational and commercial catches used in this assessment are
1271 described in detail in the 1.5 section.

1272 The bias adjustment for recruitment deviations did not exist in SS2 (version 1.19). We set
1273 1973-2012 as the range of years with full bias adjustment to span the time series that was
1274 modeled.

1275 The previous assessment modeled selectivity of the commercial fleet as logistic curve, and
1276 both parameters for the logistic selectivity were estimated. Selectivity for the onboard CPVF

1277 survey and recreational fleet were modeled using the double logistic. The current assessment
1278 uses the six parameter double normal for all fleets for which selectivity is estimated and not
1279 mirrored. The MRFSS dockside CPFV surveys and the CPFV onboard observer surveys are
1280 mirrored to the recreational fishing fleets, north and south of Point Conception, respectively.

1281 The 2005 assessment did not include any time blocks. This assessment includes two time
1282 blocks for the commercial fleet (1916-1998 and 1999-2018). A 10-inch minimum size limit
1283 was placed on the commercial fleet in 1999, which was reflected in the CALCOM length
1284 composition data. No additional time blocks were added for the recreational fleet. GBYR
1285 are a minor component of the nearshore rockfish complex and no significant changes were
1286 detected in the landings or length composition during the time when regulations changed
1287 (1999-2002).

1288 The 2005 assessment considered two candidate fishery-dependent indices of abundance, the
1289 Deb Wilson-Vandenberg onboard observer CPFV survey and a dockside intercept survey
1290 from MRFSS and RecFIN from 1983-2003. However, the dockside index was removed at the
1291 request of the STAR panel, citing “did not provide a reliable measure of relative abundance
1292 due to changes in regulations and fishery targeting during the 1990s-2000s.” The current
1293 assessment uses a version of the MRFSS database that has been more robustly aggregated to
1294 the trip level. Starting in 1999, the CDFW began the onboard observer program (described
1295 in the indices of abundance). Once the program ramped up by the mid-2000s, almost all of
1296 the CPFV groundfish trips sampled as onboard observer trips were also sampled as angler
1297 intercept surveys, i.e., dockside interviews. Using both the onboard observer data and the
1298 dockside interviews for this time period would result in developing indices from the same
1299 fish. The onboard observer program provides greater detail in terms of catch and location
1300 than the dockside sampler examined catch. The onboard observer indices do not include the
1301 years 1999 and 2000 due to the number of regulation changes occurring in those two years.

1302 The fishery-independent indices are all new for this assessment; the PISCO kelp forest fish
1303 survey and the CCFRP hook-and-line survey.

1304 Maturity was changed for this assessment based upon newly available data described in the
1305 biological specifications of this assessment.

1306 The 2005 assessment pre-STAR base model fixed steepness for gopher rockfish at 1.0, which
1307 was then changed to 0.65 (the Dorn prior at the time) during the STAR panel. In this
1308 assessment, steepness was set at 0.72, the mean of the prior developed from a meta-analysis of
1309 West Coast groundfish, with a standard deviation of 0.16 (see Accepted Practices Guidelines
1310 for Groundfish Stock Assessments in the supplemental material).

1311 The prior for female natural mortality was updated to the median of the prior from a meta-
1312 analysis conducted by Owen Hamel (see Accepted Practices Guidelines for Groundfish Stock
1313 Assessments in the supplemental material). Assuming a maximum age of 28 years, the
1314 median of the prior is 0.211138, close to the fixed value used in the 2005 assessment of 0.2.

1315 Due to the fact that the 2005 model only included gopher rockfish and excluded the area
1316 south of Point Conception, a complete bridge model was not developed. Comparison of
1317 the 2005 input data, catch streams, and indices are provided throughout the document in
1318 appropriate sections.

1319 **2.3.2 Summary of Data for Fleets and Areas**

1320 There are 12 fleets in the base model. They include:

1321 *Commercial*: The commercial fleets include two separate fleets, one for GBYR landed (all
1322 gears combined), and one for commercial dead discards.

1323 *Recreational*: The recreational fleets include two fleets, one for north of Point Conception
1324 and one for south of Point Conception (all mode combined).

1325 *Fishery-Dependent Surveys*: There are five fishery-dependent survey fleets, one each for
1326 north and south of Point Conception from the MFRSS CPFV dockside survey, one each
1327 for north and south of Point Conception from the CDFW/Cal Poly onboard observer survey,
1328 and one from the Deb Wilson-Vandenberg CPFV onboard observer survey that represents
1329 north of Point Conception only.

1330 *Research*: There are third main sources of fishery-independent data available the CCFRP
1331 survey the PISCO kelp forest fish survey. A third survey fleet is included as a “dummy”
1332 fleet to allow incorporation of additional conditional age-at-length composition data from the
1333 Zaitlin and Abrams theses, the Pearson groundfish cruise, and the special study conducted
1334 during the SWFSC’s juvenile rockfish and ecosystem cruise. This dummy fleet includes 1,067
1335 ages of gopher and black-and-yellow rockfish. This dummy fleet does not have any length or
1336 catches associated with it.

1337 **2.3.3 Other Specifications**

1338 Stock synthesis has a broad suite of structural options available. Where possible, the ‘default’
1339 or most commonly used approaches are applied to this stock assessment. The assessment
1340 is a one-sex model, as no significant differences in growth between males and females was
1341 detected in external analyses.

1342 The length composition data for some years and fleets was small, and may not be represen-
1343 tative of the total catch. Length composition data were removed from the model if fewer
1344 than 20 fish were measured in a given year and fleet. From 1985-1989, two surveys measured
1345 fish from the recreational party/charter fleet, the Ally et al. (Ally et al. 1991) onboard
1346 observer survey and the dockside intercept survey. The number of trips and fish sampled by
1347 the onboard observer survey was far greater than the RecFIN survey and were used in the

1348 model. Initial input sample sizes were also capped at 400 for each set of length composition
1349 data.

1350 The time-series of landings begins in 1916 for the commercial fleet and in 1928 for the
1351 recreational fleet. This captures the inception of the fishery, so the stock is assumed to be
1352 in equilibrium at the beginning of the modeled period.

1353 The internal population dynamics model tracks ages 0-28, where age 28 is the ‘plus-group.’
1354 There are relatively few observations in the age compositions that are greater than age 28.
1355 The population length bins and the length composition length bins are set at 1-cm bins from
1356 fish 4-40 cm.

1357 The extra standard deviation parameter was added to all indices except the Deb Wilson-
1358 Vandenberg CPFV onboard observer index and the MRFSS dockside index for north of Point
1359 Conception that both had relatively large estimated variances associated with them. The
1360 extra parameter was explored, but estimated to be on the lower bound, and was removed for
1361 the final base model. All other indices, both recent recreational onboard observer indices,
1362 CCFRP, PISCO, and the MRFSS dockside index south of Point Conception, were estimated
1363 with relatively small variances (10-20%) from their respective indices. Extra variance was
1364 estimated for these indices in the base model.

1365 The following likelihood components are included in this model: catch, indices, discards,
1366 length compositions, age compositions, recruitment, parameter priors, and parameter soft
1367 bounds. See the SS technical documentation for details (Methot et al. 2019).

1368 Electronic SS model files including the data, control, starter, and forecast files can be found
1369 on the [PFMC ftp site](#).

1370 2.3.4 Modeling Software

1371 The STAT team used Stock Synthesis 3 version 3.30.13.09 (published on 6/28/2019) by
1372 Dr. Richard Methot at the NWFSC. This most recent version was used, since it included
1373 improvements and corrections to older versions. The r4SS package (GitHub release number
1374 v1.35.1) was used to post-process output data from Stock Synthesis.

1375 2.3.5 Data Weighting

1376 Length composition and conditional-age-at-length (CAAL) compositions sample sizes for the
1377 base model were tuned by the “Francis method,” based on equation TA1.8 in Francis (2011),
1378 and implemented in the r4ss package. This approach involves comparing the residuals in the
1379 model’s expected mean length with respect to the observed mean length and associated
1380 uncertainty derived from the composition vectors and their associated input sample sizes.

1381 The sample sizes are then tuned so that the observed and expected variability are consistent.
1382 After adjustment to the sample sizes, models were not re-tuned if the bootstrap uncertainty
1383 value around the tuning factor overlapped 1.0.

1384 As outlined in the Best Practices, a sensitivity run was conducted with length and
1385 conditional-age-at-length (CAAL) compositions were re-weighted using the Ianelli-
1386 McAllister harmonic mean method (McAllister and Ianelli [1997](#)). Additionally, weighting
1387 using the Dirichlet-Multinomial likelihood, that includes an estimable parameter (theta)
1388 that scales the input sample size, was explored. However, the model did not converge
1389 when the Dirichlet-Multinomial likelihood was applied to a number of the fleets with
1390 composition data. Given this, and the current challenges with this method described in the
1391 Stock Synthesis manual (Methot et al. [2019](#)), the Francis weightings were applied in the
1392 base model.

1393 A series of sensitivities were conducted to determine the need to estimate extra variability
1394 parameters were estimated and added to the survey CPUE indices, and described below in
1395 the Estimated Parameters section.

1396 2.3.6 Priors

1397 The log-normal prior for female natural mortality were based on a meta-analysis completed
1398 by Hamel ([2015](#)), as described under “Natural Mortality.” Natural mortality was estimated
1399 using with a prior of, 0.211 for an assumed maximum age of 28.

1400 The prior for steepness (h) assumes a beta distribution with parameters based on an update
1401 for the Thorson-Dorn rockfish prior (Dorn, M. and Thorson, J., pers. comm.), which was
1402 endorsed by the Science and Statistical Committee in 2019. The prior is a beta distribution
1403 with $mu=0.72$ and $sigma=0.16$. Steepness is fixed in the base model at the mean of the
1404 prior.

1405 2.3.7 Estimated and Fixed Parameters

1406 A full list of all estimated and fixed parameters is provided in Tables [23](#). Time-invariant,
1407 growth is estimated in this assessment, with all SS growth parameters being estimated. The
1408 log of the unexploited recruitment level for the Beverton-Holt stock-recruit function is treated
1409 as an estimated parameter. The early annual recruitment deviations begin in 1960, with the
1410 main recruitment deviations estimated from 1972-2018. The survey catchability parameters
1411 are calculated analytically (set as scaling factors) such that the estimate is median unbiased,
1412 which is comparable to the way q is treated in most groundfish assessments.

1413 The base model has a total of 111 estimated parameters in the following categories:

- 1414 ● Natural mortality
 - 1415 ● Equilibrium recruitment (R_0) and 71 recruitment deviations
 - 1416 ● Stock recruitment autocorrelation parameter
 - 1417 ● Five growth parameters
 - 1418 ● Five index extra standard deviation parameter, and
 - 1419 ● 27 selectivity parameters
- 1420 The estimated parameters are described in greater detail below and a full list of all estimated
 1421 and parameters is provided in Table 23.
- 1422 *Growth.* Five growth parameters were estimated for the one-sex model: three von Bertalanffy parameters and two parameters for CV as a function of length-at-age related to variability in length-at-age for small and large fish.
- 1425 *Natural Mortality.* The estimated natural mortality of 0.212 is close to the mean of the prior,
 1426 0.193.
- 1427 *Selectivity.* Selectivity for all fleets was estimated as double-normal.
- 1428 Selectivity was estimated as asymptotic for the commercial fleet, with one time block.
 1429 Asymptotic selectivity was also estimated for both recreational fleets, Deb Wilson-
 1430 Vandenberg's onboard observer survey, and the PISCO. Three parameters were estimated
 1431 for each of these fleets, the peak, the ascending width, and the selectivity at the first bin.
- 1432 Dome-shaped selectivity was estimated for the commercial discard fleet and the CCFRP
 1433 survey. Five of the size parameters were estimated for the commercial discard selectivity
 1434 (selectivity at the last bin was fixed). Four parameters were estimated for the CCFRP
 1435 length compositions (selectivity at the first and last bins was fixed).
- 1436 *Other Estimated Parameters.* Early recruitment deviations for the base model are estimated
 1437 from 1960-1972, with the main recruitment deviations estimated from 1978 to 2018. The
 1438 base model also included estimated recruitment deviations for the forecast years, although
 1439 these have no impact on the model estimates for the current year.
- 1440 Many variations of the base case model were explored during this analysis. Sensitivities to
 1441 asymptotic vs. domed selectivity were explored for the appropriate fisheries, e.g. commercial
 1442 fisheries and surveys, as well as estimating selectivity and mirroring fleet selectivities. Time
 1443 blocked selectivity without the time block from 1999-2019 for the recreational fisheries was
 1444 investigated.
- 1445 Much time was also spent tuning the advanced recruitment bias adjustment options.
 1446 Sensitivities were performed to each of the thirteen advanced options for recruitment, e.g.,

1447 early recruitment deviation start year, early recruitment deviation phase, years with bias
1448 adjustments, and maximum bias adjustment. The final base model sets the first year of
1449 recruitment deviations just prior to when the majority of fishery/survey length composition
1450 are available.

1451 Initial runs showed that the estimated recruitments were highly auto-correlated.
1452 Therefore, an auto-correlation parameter was late estimated and its value was estimated to
1453 be positive and significantly different from zero.

1454 Several models were also investigated where steepness and natural mortality were either
1455 estimated, fixed at their respective priors.

1456 *Other Fixed Parameters.* The stock-recruitment steepness is fixed at the SSC approved
1457 steepness prior for rockfish of 0.72.

1458 2.4 Model Selection and Evaluation

1459 2.4.1 Key Assumptions and Structural Choices

1460 Key assumptions in the model are that it is appropriate to model gopher and black-and-yellow
1461 rockfish as a complex. The catch histories are inseparable at this time, especially for
1462 the early commercial landings. The biological information available also precluded complete
1463 analyses of difference in growth, i.e., the majority of black-and-yellow rockfish aged were
1464 small fish and small fish were lacking for gopher rockfish. Data from both species were used
1465 to provide a complete picture of the growth curve.

1466 The assessment is a one area model with fleets as areas for the recreational fishery. There
1467 were only a handful of aged gopher rockfish from south of Point Conception, and not enough
1468 other biological information available that would have justified a multi-area model.

1469 2.4.2 Alternate Models Considered

1470 A number of models were run with different catch histories for the recreational fleet south of
1471 Point Conception, given that the catch histories were modified from the original data. None
1472 of the alternatives explored altered the model at any significant level due to the fact that
1473 the recreational catches south of Point Conception are relatively small. Results from select
1474 sensitivity runs compared to the base model are in Table 26.

1475 Two sensitivities were also performed altering the commercial discard catch history. The
1476 discard catch was set to zero for all years prior to 2004, the year when WCGOP estimates
1477 were first available, and to a constant rate of 17% of the commercial landings, the maximum

1478 discard rate observed in the WCGOP data. Neither of these sensitivities resulted in any
1479 significant change to the model outputs.

1480 Sensitivity of the model to the spawning and settlement months were also explored. The
1481 base model originally set settlement month to January. Both gopher and black-and-yellow
1482 rockfish settle at a small size (~2 cm) and over a course of several months. After exploring the
1483 young-of-the-year length data made available by Diana Baetscher, the timing of settlement
1484 was moved to July for the base model, when the majority of GBYR are 4 cm, the size of the
1485 smallest length bin. The change of the timing of settlement had little effect on the model
1486 results.

1487 Runs of the base case model estimating steepness were also considered.

1488 A sensitivity of the model to using the commercial length composition data from PacFIN
1489 was also considered. The fits to the changed only slightly, (increasing depletion from 0.46
1490 to 0.48) but given the concerns outlined in the discussion on commercial length composition
1491 the base model includes the commercial length compositions from CALCOM.

1492 Sensitivities were developed to look at alternate selectivity patterns for the the commercial
1493 discard fleet and the CCFRP survey. Neither of the length compositions for these fleets
1494 observed larger fish. A time block for the commercial discard fishery was not considered
1495 since no length composition of discarded fish were available prior to 2004.

1496 2.4.3 Convergence

1497 Model convergence was determined by starting the minimization process from dispersed val-
1498 ues of the maximum likelihood estimates to determine if the model found a better minimum.
1499 Jitter is a SS option that generates random starting values from a normal distribution lo-
1500 gistically transformed into each parameter's range (Methot et al. 2019). This was repeated
1501 240 times and the minimum was reached in 97% of the runs (Table 22). The model did not
1502 experience convergence issues, e.g., final gradient was below 0.0001, when reasonable starting
1503 values were used and there were no difficulties in inverting the Hessian to obtain estimates of
1504 variability. We did sensitivity runs for convergence by changing the phases for key estimated
1505 parameters; neither the total log-likelihood nor the parameter estimates changed.

1506 2.5 Response to the Current STAR Panel Requests

1507 To be populated after the STAR panel.

1508 **2.6 Base Case Model Results**

1509 The following description of the model results reflects a base model that was developed prior
1510 to the STAR panel (this section will be updated after the STAR panel). The base model
1511 parameter estimates and their approximate asymptotic standard errors are shown in Table
1512 [23](#) and the likelihood components are in Table [24](#). Estimates of derived reference points
1513 and approximate 95% asymptotic confidence intervals are shown in Table [e](#). Time-series of
1514 estimated stock size over time are shown in Table [25](#).

1515 Steepness of the assumed Beverton-Holt stock-recruitment relationship was fixed at 0.72,
1516 and natural mortality was estimated to be 0.22.

1517 **2.6.1 Parameter Estimates**

1518 The base model produces estimates of growth parameters different from the external esti-
1519 mates. The external estimate of the von Bertalanffy growth coefficient k was 0.247, whereas
1520 the internal estimate was much lower at 0.121. Using the Schnute parameterization with the
1521 age for L1 set at 2 and L2 at 23, the external estimates of lengths at Amin and Amax were
1522 13.80 and 28.22, respectively. The internal estimates of the lengths for Amin and Amax were
1523 9.72 and 28.36, respectively. Natural mortality was estimated in the base model and natural
1524 mortality and the growth parameter k are negatively correlated. The model sensitivity to
1525 growth and natural mortality are explored in the sensitivities.

1526 The additional survey variability (process error added directly to each year's input variabil-
1527 ity) for all surveys was estimated within the model.

1528 Selectivity curves were estimated for the fishery and survey fleets. The estimated selectivities
1529 for all fleets within the model are shown in Figure [41](#). The commercial fishery selectivities
1530 are all asymptotic. Maximum selectivity for the commercial fleet is reached at 34 cm from
1531 1916-1998 and also selected fish smaller than recent years. The implementation of the 10-
1532 in size limit resulted in a steeper selectivity curve, with fish fully selected at 31 cm from
1533 1999-2018 (Figure [42](#)).

1534 The commercial discard fleet did not observe any fish over 36 cm in the 14 years of available
1535 data. The majority of the nearshore fishery for GBYR is the live fish fishery, and fishermen
1536 are fishing shallower waters in order to ensure that the landed fish remain alive. The larger
1537 GBYR likely reside in waters deeper than typically fished by this fleet.

1538 The recreational fleet north of Point Conception selects the largest fish of the other fleets,
1539 with full selectivity at 34 cm. Fish south of Point Conception encountered in the recreational
1540 fleet were noticeably smaller, and fully selected at 29 cm.

1541 The two fishery-independent surveys sample different habitats and depth ranges. The PISCO
1542 study only samples in 0-20 m depth and observes small young-of-the-year fish and adults,

1543 but not the 10-17 cm size range. The asymptotic selectivity for the PISCO survey does not
1544 go to zero on the ascending side since the young-of-the-year fish are observed. The CCFRP
1545 survey does not see the larger size classes, possibly due to the maximum survey depth fished
1546 to reduce barotrauma. Dome shaped selectivity was estimated for this survey.

1547 The additional survey variability (process error added directly to each year's input variabil-
1548 ity) for all surveys was estimated within the model. The model estimated a small added
1549 variance for MRFSS dockside recreational index north of Point Conception that was then
1550 turned off for the final base model. The added variance for Deb's onboard observer survey
1551 was estimated at 0.075566 but the model presented stability issues during jittering when the
1552 variability was turned off. Therefore, it was turned on for the final base model, and can be
1553 explored further. The added variances were highest for the recreational onboard observer
1554 survey north of Point Conception (0.234) and south of Point conception (0.598), the MRFSS
1555 dockside south of Point Conception (0.282), PISCO (0.2), and CCFRP (0.187).

1556 Recruitment deviations were estimated from 1978-2018 (Figure 43). Estimates of recruitment
1557 suggest that GBYR are characterized by cyclical years of high and low recruitment (Figure
1558 44). The years of highest estimated recruitment were in the early 1990s, followed by a period
1559 of below average recruitment, and another high recruitment pulse in the late 2010s. The
1560 PISCO kelp forest fish survey is the only fishery-independent survey that observed young-
1561 of-the-year GBYR in this assessment.

1562 The stock-recruit curve resulting from a fixed value of steepness is shown in Figure 45.
1563 The stock has not been depleted to a low enough level that would inform the estimation of
1564 steepness. Steepness was not estimated in this model, and profiles over steepness values are
1565 discussed below.

1566 2.6.2 Fits to the Data

1567 Model fits to the indices of abundance, fishery length composition, survey length composition,
1568 and conditional age-at-length observations are all discussed below. The full r4ss plotting
1569 output is available in the supplementary material.

1570 The fits to the five fishery-dependent and two fishery-independent survey indices are shown
1571 in Figures 46 - 52. The majority of the indices represent the area north of Point Conception
1572 only and not all of these were fit well by the assessment model. The MRFSS recreational
1573 dockside survey index north of Point Conception spanning the 1980s-1990s was fit well by the
1574 model without added variance, but relatively flat, and is not a very informative index. The
1575 index for Deb's CPFV onboard observer survey spanning 1988-1998 was well fit and indicates
1576 an increase in relative abundance in the last year of the survey. The current recreational
1577 CPFV onboard observer survey north of Point Conception from 2001-2018 was relatively
1578 well fit, except for the decline suggested 2013 and 2014. The increase in relative abundance
1579 observed in 2018 was not fit by the model, even with the added variance.

1580 The fishery-dependent indices for north of south of Point Conception were both relatively
1581 flat. The MRFSS CPFV dockside survey index was relatively well fit and indicated an
1582 increase in the last two years of the survey, 1998-1999. The current onboard observer survey
1583 representing 2001-2018 showed very little trend in the estimated CPUE, and the variance
1584 added to this survey was the highest for all indices.

1585 The fishery-independent PISCO kelp forest fish survey index indicates a cyclical trend that
1586 was not captured by the model fit. The fit to the index is relatively flat This may be in part
1587 due to the observation of both young-of-the-year, small juveniles, and adults in the survey.
1588 An alternative index of abundance teasing apart the two life stages will be developed and
1589 presented at the STAR panel.

1590 The model was not able to capture the trends observed in the fishery-independent CCFRP
1591 hook-and-line survey. The index suggested the same depressed relative abundance in 2013
1592 as the fishery-dependent onboard observer survey, that was also not captured here by the
1593 fit. The increasing trends in abundance from 2016-2018 was also not captured by the model
1594 fit, and the fit suggests a declining trend over the entire time series from 2007-2018.

1595 Fits to the length data are shown based on the proportions of lengths observed by year and
1596 the Pearson residuals-at-length for all fleets. Detailed fits to the length data by year and
1597 fleet are provided in Appendix 8. Aggregate fits by fleet are shown in Figure 53. Overall,
1598 the length composition all fit well. The fit to the the commercial discard length composition
1599 was underestimated at the peak, but otherwise captures the observations well. The same
1600 is true for one of the peaks at 25 cm for the PISCO data, that were the nosiest of all the
1601 length composition data. There are a handful of years within some of the annual length
1602 composition data that were not particularly well fit, e.g., 1980 and 1996 for RecSouth, but
1603 these were usually due to high frequencies of fish in a small number of length bins.

1604 The age data were also weighted according to Francis weighting which adjust the weight given
1605 to a data set based on the fit to the mean age by year. The mean age of the recreational
1606 fleet declined from 1980 to 1986, and the mean for 2017 was the highest of all years (Figure
1607 54). The conditional age data from the CCFRP data was not well fit for the earliest years
1608 in the data, but was reasonably well fit for the last four years of data (Figure 55). The
1609 conditional length composition data from the ‘dummy’ fleet was well fit, although heavily
1610 down-weighted. Age data in this fleet are from a number of sources and sampling programs
1611 (Figure 56).

1612 2.6.3 Uncertainty and Sensitivity Analyses

1613 A number of sensitivity analyses were conducted, including:

- 1614 1. Fixing natural mortality at the prior of 0.193

- 1615 2. Fixing the von Bertalanffy k at the external estimate of 0.247
1616 3. Using the PacFIN expanded length composition data
1617 4. Data weighting scenarios including unweighted, harmonic means (McAllister-Ianelli
1618 method), and Francis weights

1619 The following sensitivities are based on the pre-STAR base model and indicate areas that the
1620 STAT identified as either areas of uncertainty or model sensitivities outlined in the Accepted
1621 Practices and Guidelines document. A summary of parameters for all sensitivity runs is in
1622 Table 26.

1623 Fixing either natural mortality or the von Bertalanffy k parameter results in a stock with
1624 higher spawning output in 2018 as compared to the base model (Figure 57).

1625 Fixing either M or k demonstrates the negative correlation between the two parameters. The
1626 von Bertalanffy k parameter is estimated at 0.12 when natural mortality (estimated at 0.21)
1627 and growth are both estimated. When natural mortality is fixed at the prior of 0.19, k is
1628 estimated at 0.14, but the two other growth parameters, L1 and L2 do not change much at
1629 all. When k is fixed to the external estimate of 0.247, natural mortality is estimated at 0.16,
1630 and the other growth parameters both decrease.

1631 Replacing the CALCOM commercial length composition data with the PacFIN length com-
1632 position results in the stock at an overall lower level of biomass than the base model. Deple-
1633 tion in the final year with the PacFIN length composition is 0.50, compared to 0.46 in the
1634 base model. A detailed discussion on the decision to use the CALCOM length composition
1635 in the base model can be found in the discussion commercial length and age data, Section
1636 (2.1.3).

1637 Data weighting is an area of uncertainty for stock assessment, and research is ongoing to
1638 determine the effects of data weighting and the most appropriate initial sample sizes for
1639 length and age composition data. The base model used the Stewart sample sizes for initial
1640 sample sizes for the fishery data and either the Stewart sample sizes or number of “trips” for
1641 the survey sample sizes. Weighting the data by the harmonic mean resulted in a model with
1642 a total likelihood between the base model, which uses the Francis method for weighting, and
1643 the model with default weights (Figure 58). The end year spawning output is almost identical
1644 for the models using harmonic means and Francic weights, both of which down-weighted the
1645 composition data.

1646 The Francis weights in the base model were stable, and did not tend to serially decrease
1647 (down-weight) any of the data sets, which has been seen in other assessments. The final
1648 base model re-weights the composition data only once. As discussed above in the data
1649 weighting section, the Dirichlet-Multinomial weighting was explored, but a model with a
1650 positive definite Hessian was not identified with the pre-STAR base model.

1651 **2.6.4 Retrospective Analysis**

1652 A 4-year retrospective analysis was conducted by running the model using data only through
1653 2018 (retro 1), 2017 (retro 2), 2016 (retro 3), and 2015 (retro 4) (Table 27). The initial
1654 population size and estimation of trends in spawning biomass in the retrospective runs
1655 were lower than the base model (Figure 59). All retrospective runs converged to the same
1656 low point in the 1990s and the diverged for the remainder of the time series. There is
1657 no conditional age-at-length composition data for 2015-2016, leading to the minor change
1658 in the age composition likelihood from Retro2 to Retro3 and Retro4 (Table 27). The age
1659 composition data in 2017 accounts for 2.5% of all available ages, and 4.5% of all fish aged were
1660 from 2018. The available length data in each year from 2015-2018 range from 4-6% of the
1661 total available length data. The PISCO kelp forest fish survey observed increased abundance
1662 of small fish from 2015-2017 (Figure C7), which are captured in all of the retrospective runs.
1663 The length compositions of all the other fleets have similar length distributions for 2015-2018
1664 (8). Additional investigations into the retrospective patters will be made by the STAT.

1665 The recruitment deviations in the more recent years shrink towards zero the more years are
1666 removed from the model (Figure 60).

1667 **2.6.5 Likelihood Profiles**

1668 Likelihood profiles were conducted for R_0 , steepness, and over natural mortality values sep-
1669 arately. These likelihood profiles were conducted by fixing the parameter at specific values
1670 and estimated the remaining parameters based on the fixed parameter value (Tables 28-29).

1671 In regards to values of R_0 , the negative log-likelihood was minimized at approximately
1672 $\log(R_0)$ of 8.5 (Table 28). The individual fleets tend to minimize at the lower bound, e.g.,
1673 CCFRP and commercial fleets, or the upper bound, e.g., PISCO and the recreational north
1674 fleets (Figure 61). The data all consistently minimize around 8.5 with a smal change in
1675 likelihood at larger values of R_0 (Figure 62). Over the range of values of R_0 , depletion
1676 ranged from 0.22-0.05 (Figure 63).

1677 For steepness, the negative log-likelihood reaches a minimum around a steepness of 0.90 for
1678 the prior and the total likelihood (Figure 65 and Table 28). The other likelihood components
1679 continue to decline as alternative values of steepness (Figure 69).

1680 Likelihood components by data source show that the commercial discard lengths, recreational
1681 south lengths, Deb's onboard observer fleets support a steepness value at the lower bound of
1682 the values explored, and the other data sources higher value for steepness (Figure 65). The
1683 relative depletion for GBYR ranges from 0.375 to 0.493 across different assumed values of
1684 steepness (Table 28).

1685 The negative log-likelihood was minimized at a natural mortality value of 0.22, slightly higher
1686 than the prior of 0.19 (Table 28 and Figure 68). The age, length, index, and prior likelihood

1687 contributions were minimized at natural mortality values around 0.22, and the recruitment
1688 contribution was minimized as the second to largest value of M run, 026. (Table 28).
1689 The relative depletion for GBYR ranged from 0.32-0.59 across alternative values of natural
1690 mortality (Figure 69).

1691 2.6.6 Reference Points

1692 Reference points were calculated using the estimated selectivities and catch distribution
1693 among fleets in the most recent year of the model, (2017). Sustainable total yield (landings
1694 plus discards) were 186 mt when using an $SPR_{50\%}$ reference harvest rate and with a 95%
1695 confidence interval of 102 mt based on estimates of uncertainty. The spawning biomass
1696 equivalent to 40% of the unfished level ($SB_{40\%}$) was 569 mt.

1697 The predicted spawning output from the base model shows an initial decline starting the
1698 1950s, is then stable, and declines steeply until 1995 (Figure 70). The spawning output then
1699 rapidly increases through the early 2000s, and has been in a decline since 2006.

1700 The 2018 spawning biomass relative to unfished equilibrium spawning biomass is above the
1701 target of 40% of unfished levels (Figure 71). The relative fishing intensity, $(1 - SPR)/(1 -$
1702 $SPR_{50\%})$, was below the management target from 1981-1998, and below the minimum stock
1703 size threshold in 1995. The stock has been above the management target since 1999.

1704 Table e shows the full suite of estimated reference points for the base model and Figure 72
1705 shows the equilibrium curve based on a steepness value fixed at 0.72.

1706 3 Harvest Projections and Decision Tables

1707 This section will be completed at or after the STAR panel.

1708 4 Regional Management Considerations

1709 While the proportion of the stock residing within U.S. waters is unknown, the assessment
1710 provides an adequate geographic representation of the portion assessed for management
1711 purposes. There is little evidence that black-and-yellow rockfish extend into Mexico, and
1712 the proportion of gopher rockfish residing south of Pt. Conception is small. While there has
1713 been work on the genetic structure between the two species, there has not been work done
1714 within each species to inform spatial structure of the populations. Given the relatively small
1715 area in the waters of California where these species occur, there is relatively little concern

₁₇₁₆ regarding exploitation in proportion to the regional distribution of abundance in the area
₁₇₁₇ assessed in this study.

₁₇₁₈ The state of California implements regional management for the recreational fleet in the
₁₇₁₉ form of five regions. Neither gopher nor black-and-yellow rockfish are a large component
₁₇₂₀ of the total recreational landings and are managed as part of a shallow nearshore rockfish
₁₇₂₁ complex. Current regional management appears appropriate for these species.

₁₇₂₂ **5 Research Needs**

₁₇₂₃ This section will be completed at or after the STAR panel.

₁₇₂₄ **6 Acknowledgments**

₁₇₂₅ This section will be completed at or after the STAR panel.

Table 7: Data filtering steps for Deb Wilson-Vandenberg's CPFV onboard observer index of abundance

Filter	Drifts	Positive Drifts
Remove errors, missing data	6691	1470
Remove 1987 (sampled only MNT), 1990-1991 low sample sizes	4283	1372
Remove reefs that never encountered GBY	4022	1372
Remove lower and upper 2.5% of time fished	3762	1300
Remove depth less than 9 m and greater than 69 m	3515	1279
Remove reefs with low sample rates	2411	1096

Table 8: Model selection for Deb Wilson-Vandenberg's CPFV onboard observer index of abundance. Bold values indicate the model selected.

Model	Lognormal	Binomial
Year	2834	3330
Year + Depth	2781	2906
Year + Reef	2716	2880
Year + Month	2839	3286
Year + Depth + Reef	2625	2488
Year + Month+ Reef	2725	2844
Year + Depth + Month	2780	2902
Year+ Depth+Month+Reef	2632	2479

Table 9: Data filtering steps for the CRFS CPFV onboard observer index of abundance for north and south of Pt. Conception.

Filter	Drifts	Positive Drifts
Data from SQL filtered for missing data	67850	9317
Remove years prior to 2001 and north of Cape Mendocino	64448	9129
Depth, remove 1% data on each tail of positive catches	50846	8955
Time fished, remove 1% data on each tail	50100	8903
Observed anglers, remove 1% data on each tail	48089	8774
Limit to reefs observering gopher/byel in at least 20 drifts	29639	8025
Limit to reefs sampled in at least 2/3 of all years	32672	7517
Limit to drifts within 1000 m of a reef	27355	7358
Put depth in 10m depth bins, remove 0-9 and 60-69 m bins	25427	7250
Start of north filtering	13792	6036
Filter to drifts within 43 m of a reef, 97% quantile	13145	5854
Make sure reefs still sampled at least 2/3 of years	12965	5796
Start of south filtering	11635	1277
Filter to drifts with $\geq 20\%$ groundfish and recheck reefs	5495	1171
Make sure reefs still sampled at least 2/3 of years	5440	1132

Table 10: Model selection for the CRFS CPFV onboard observer index of abundance for north of Pt. Conception. Bold values indicate the model selected.

Model	Lognormal	Binomial
Year	14135	17531
Year + Month	14120	17529
Year + Depth	13953	17025
Year + Reef	14126	17293
Year + Month + Depth	13951	17027
Year + Month + Depth + Reef	13921	16674

Table 11: Model selection for the CRFS CPFV onboard observer index of abundance for south of Pt. Conception. Bold values indicate the model selected.

Model	Lognormal	Binomial
Year	2798	5490
Year + Month	2799	5487
Year + Depth	2744	5159
Year + Reef	2653	5390
Year + Depth + Reef	2652	5071
Year + Depth + Reef + Month	2663	5072

Table 12: Data filtering steps for the PISCO dive survey.

Filter	Transects	Positive Transects
Remove missing data and retain only bottom transects	22,055	6,330
Remove month of June - few samples	21,941	6,318
Remove dives earlier than 2004 for UCSB and 2001 for UCSC	20,659	6,165
Keep sites sampled in at least half of all years (UCSC and UCSB separate)	14,721	4,097
Keep sites observing GBYR in at least half of all years	12,139	4,002
Remove transects denoted as old, no longer sampled	10,712	3,268
Subset to just UCSC sites	5,686	2,939
Use only consistently sampled sites	3,231	1,729
Collapse repeated transects	1,928	1,487

Table 13: Model selection for the PISCO dive survey data.

Model	AIC
Year	5,687
Year + Month	5,672
Year + Month + Site	5,623
Year + Month + Site + Zone	5,512

Table 14: Data filtering steps for the fishery-independent CCFRP hook-and-line survey.

Filter	Drifts	Positive Drifts
All data	5,886	Drift and catch data not merged
Remove missing data and cells not sampled consistently at Piedras Blancas	4,942	3,857
Remove cells that never encountered GBYR	4,934	3,857
Remove depth bins with little or no sampling (keep 5-39 m)	4,920	3,848

Table 15: Model selection for the fishery-independent CCFRP hook-and-line survey.

Model	AIC
Year	23,212
Year + Month	23,214
Year + Depth	22,901
Year + Depth + Site	22,642
Year + Depth + Site + MPA/REF	22,341

Table 16: Data filtering steps for the MRFSS dockside intercept survey index of abundance for north and south of Pt. Conception.

Filter	Trips	Positive Trips
All data	10,392	1,061
Remove north of Cape Mendocino	10,327	1,061
Remove trips targetting offshore species	10,122	1,061
Start northern filtering	2,788	620
Remove species that never co-occur and not present in at least 1% of all	2,788	620
Stephens-MacCall filter (keep all positives - selected filter)	806	620
Alternate Stephens-MacCall filter (keep only above threshold)	623	437
Remove years after 1999 due to regulation changes and with fewer than 20 trips	544	220
Start southern filtering	7,334	441
Remove species that never co-occur and not present in at least 1% of all	7,334	441
Stephens-MacCall filter (keep all positives - selected filter)	687	441
Alternate Stephens-MacCall filter (keep only above threshold)	430	184
Remove years after 1999 due to regulation changes and with fewer than 20 trips	475	342

Table 17: Model selection for the MRFSS dockside intercept survey north of Pt. Conception. Bold values indicate the model selected.

Model	AIC
Year	1,481
Year + Region	1,429
Year + Region + Area_X	1,403
Year + Region + Area_X + Wave	1,397

Table 18: Model selection for the MRFSS dockside intercept survey south of Pt. Conception. Bold values indicate the model selected.

Model	Lognormal	Binomial
Year	911	552
Year+ Wave	908	538
Year + Wave + Area_X	905	540
Year + Wave + Area_X + SubRegion	903	537
Year + Wave + SubRegion	908	536

Table 19: Contingency table for the Stephens-MacCall filtering for the MRFSS dockside CPFV index for GBYR north of Pt. Conception.

	GBYR absent	GBYR present
Above 0.4	186	437
Below 0.4	1982	183

Table 20: Contingency table for the Stephens-MacCall filtering for the MRFSS dockside CPFV index for GBYR south of Pt. Conception.

	GBYR absent	GBYR present
Above 0.22	246	184
Below 0.22	6647	257

Table 21: Summary of available age data. All ages except the commercial ages were used in the assessment.

Project	Source	Years	Region	Gear	Black-and-yellow	Gopher
Port sampling	Commercial	2009-2010; 2018	Bodega; Morro Bay	hook-and-line	0	46
CDFW sampling	Recreational	1978; 1980; 1982-1986	Morro Bay; San Francisco	hook-and-line	0	138
Cal Poly onboard observer	Recreational	2018	Morro Bay	hook-and-line	0	36
E.J.'s trap survey	Research	2012	Monterey	trap	1	25
Zaitlin thesis	Research	1983-1986	Monterey	spear	491	0
Pearson groundfish cruise	Research	2002-2005	Monterey	hook-and-line	0	118
Hanan CPFFV survey	Research	2003-2004	Morro Bay; Santa Barbara	hook-and-line	0	189
Juv. rockfish cruise special study	Research	2004-2005	Monterey	hook-and-line	0	79
CCFRP	Research	2007-2013	Central CA	hook-and-line	7	1,191
CCFRP trap	Research	2008-2009	Central CA	trap	0	87
Abrams thesis	Research	2010-2011	Fort Bragg	hook-and-line	0	59
Total					499	1,968

Table 22: Results from 100 jitters from the base case model.

Description	Value

₁₇₂₇ 8 Figures

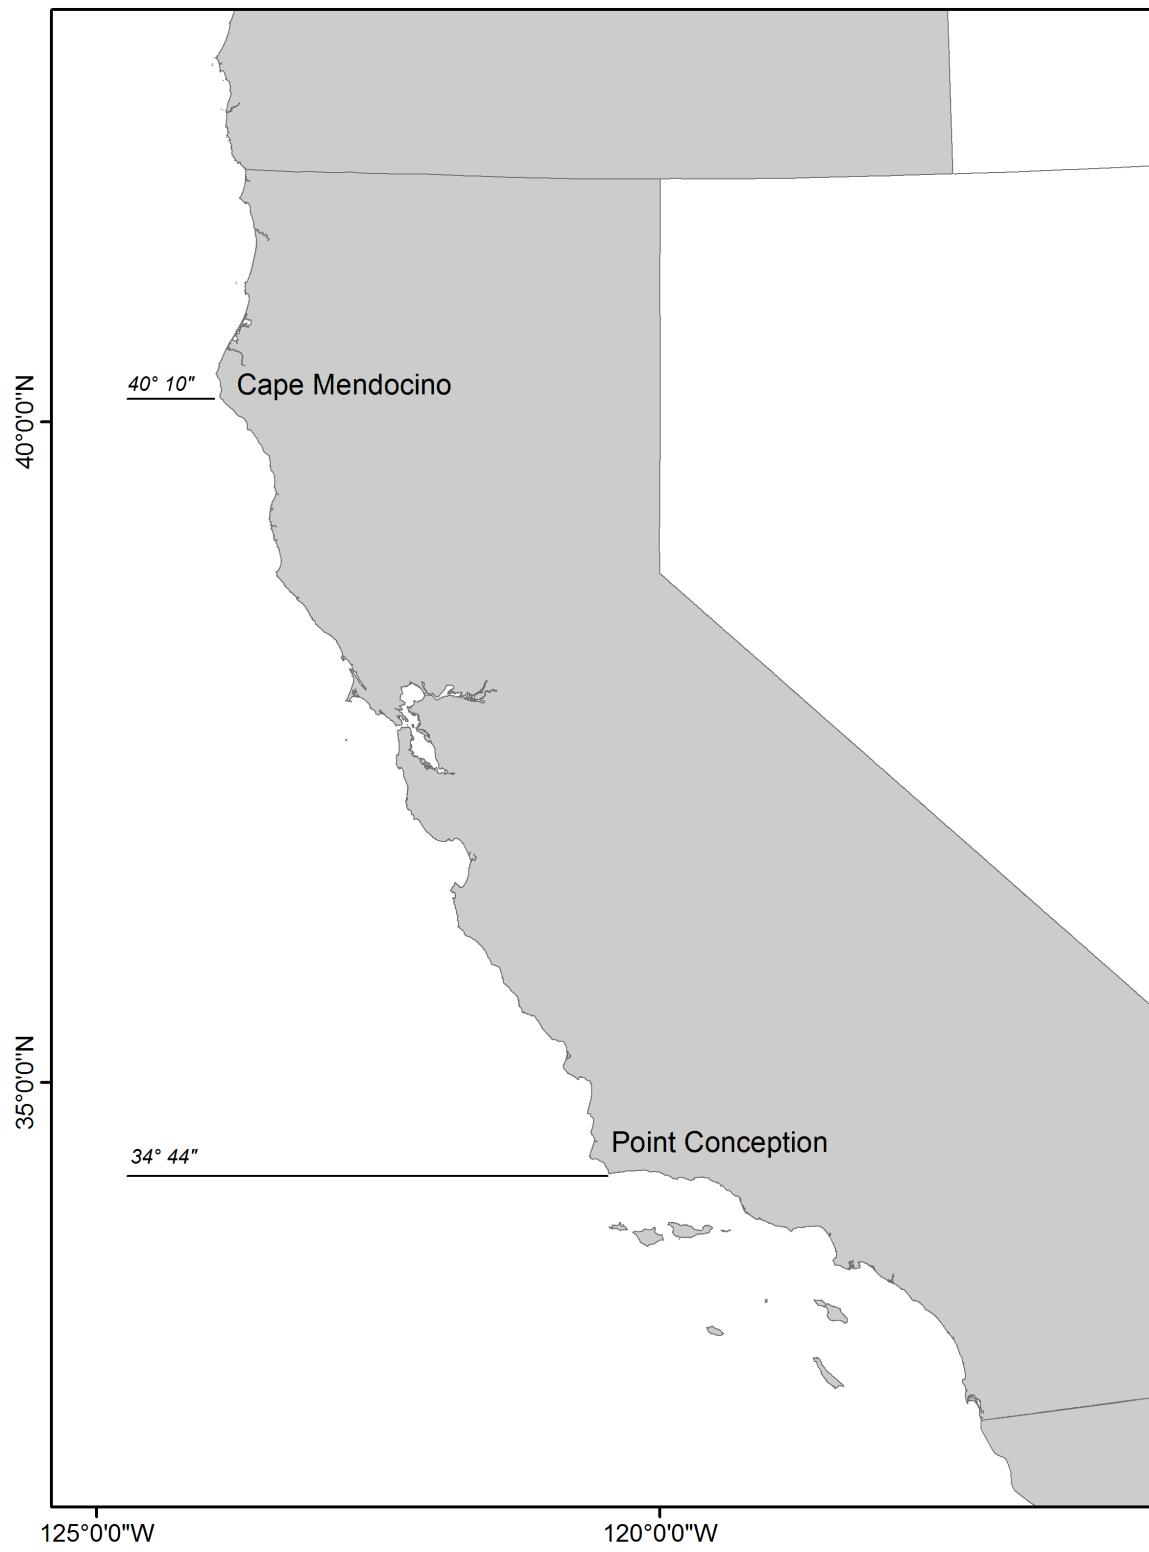

Figure 1: Map showing the management area for gopher and black-and-yellow rockfish from Cape Mendocino to the U.S.-Mexico border.

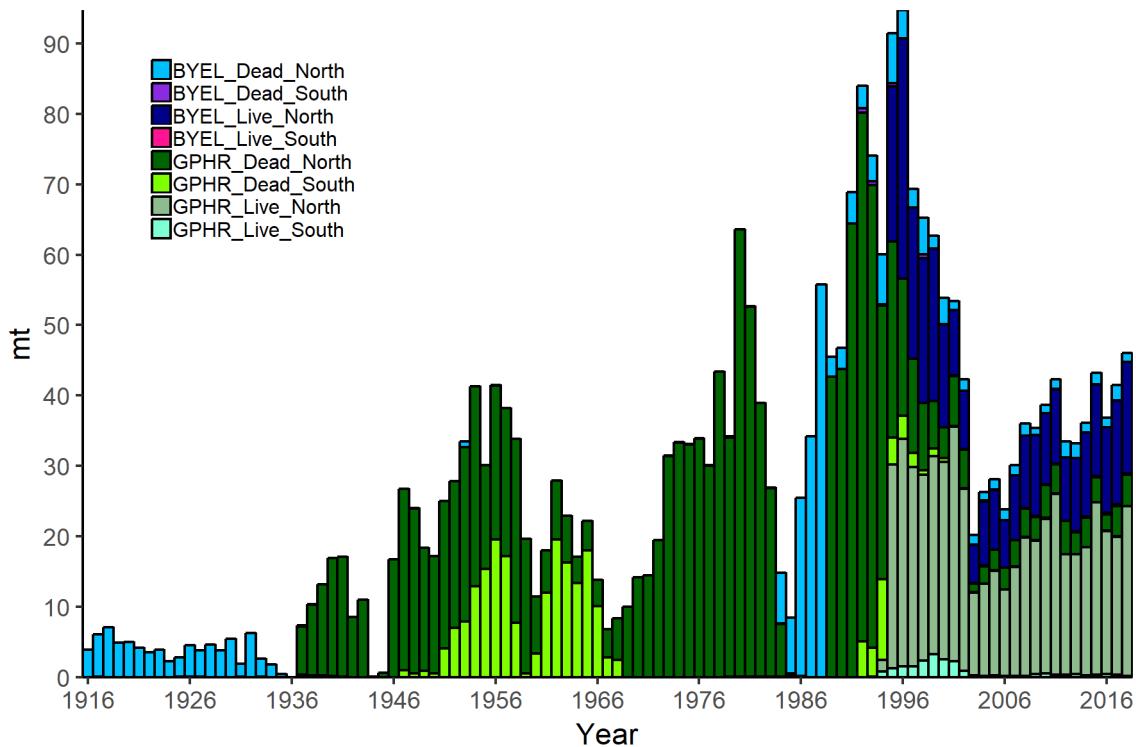

Figure 2: Commercial landings for gopher (GPHR) and black-and-yellow (BYEL) rockfishes landed live and dead north and south of Point Conception. All catch time series were combined for the assessment into one commercial fleet.

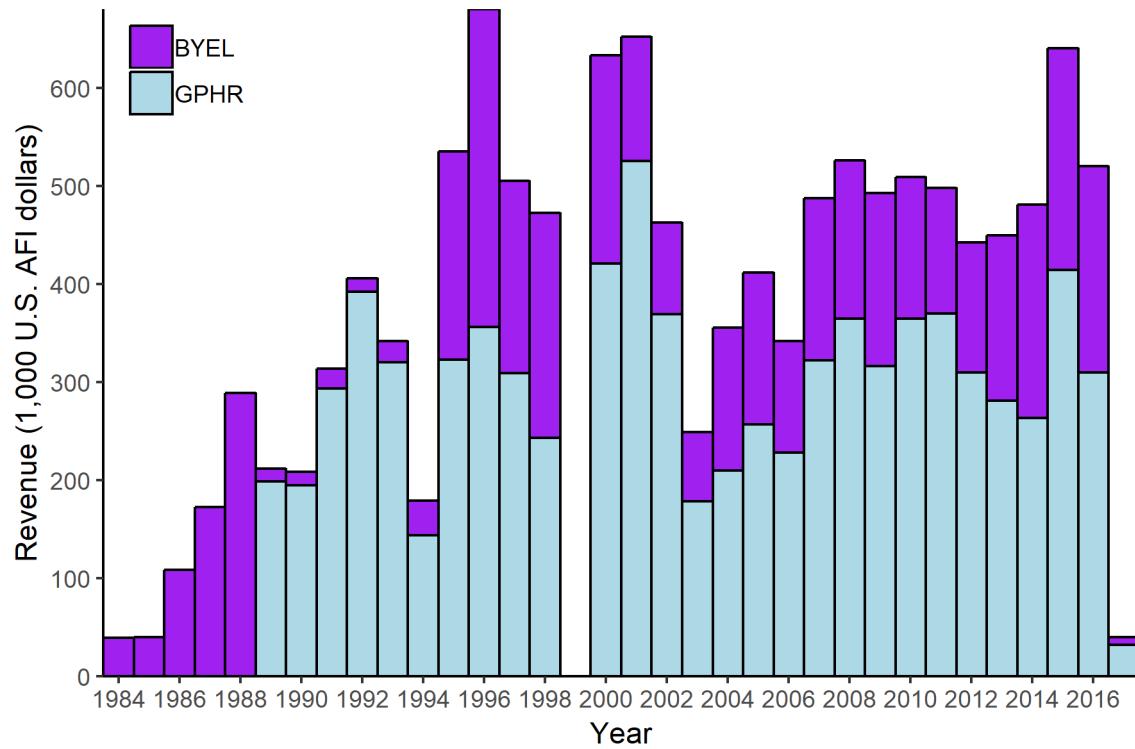

Figure 3: Annual ex-vessel revenue, adjusted for inflation (AFI) in thousands of dollars for gopher and black-and-yellow rockfish.

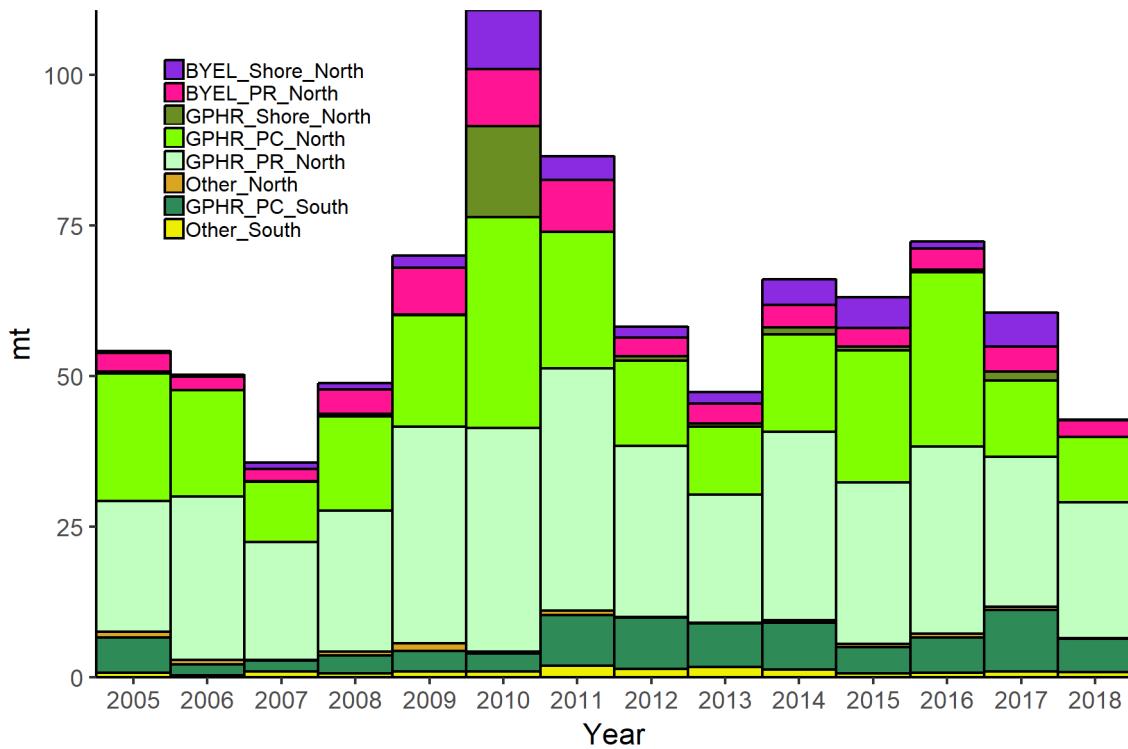

Figure 4: Recreational total mortality for gopher rockfish (GPHR) and black-and-yellow (BYEL) rockfish from the CDFW CRFS sampling era by mode and split north and south of Point Conception.

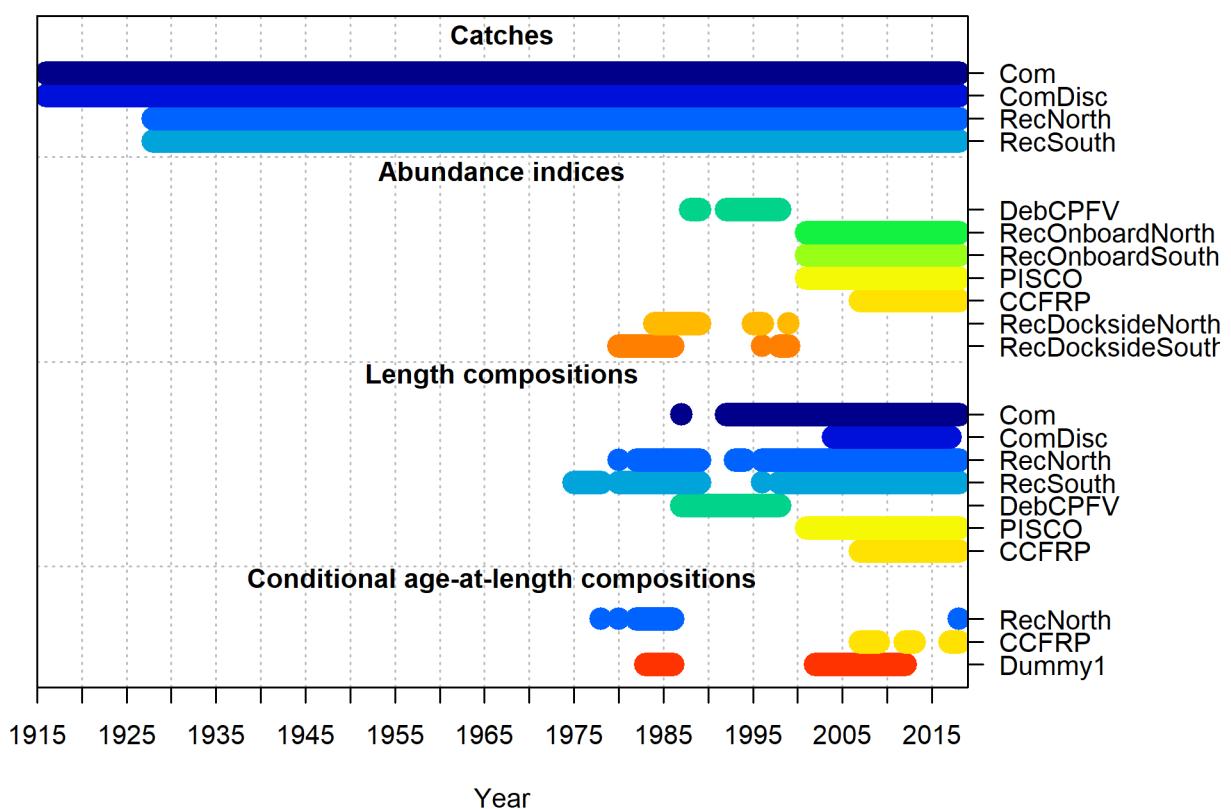

Figure 5: Summary of data sources used in the model.

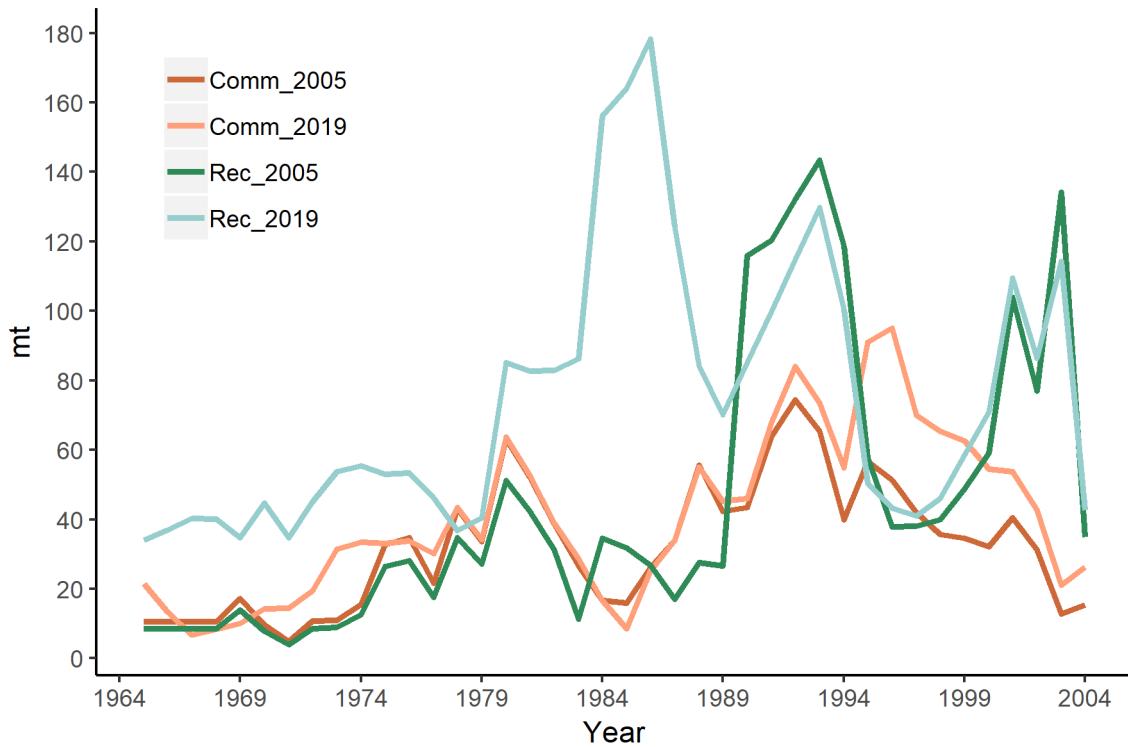

Figure 6: Comparison of the recreational and commercial fishery landings from the 2005 assessment to this 2019 assessment. Note that the 2019 assessment includes both gopher and black-and-yellow rockfish where the 2005 assessment represents gopher rockfish only. The 2005 assessment also did not include landings from south of Point Conception.

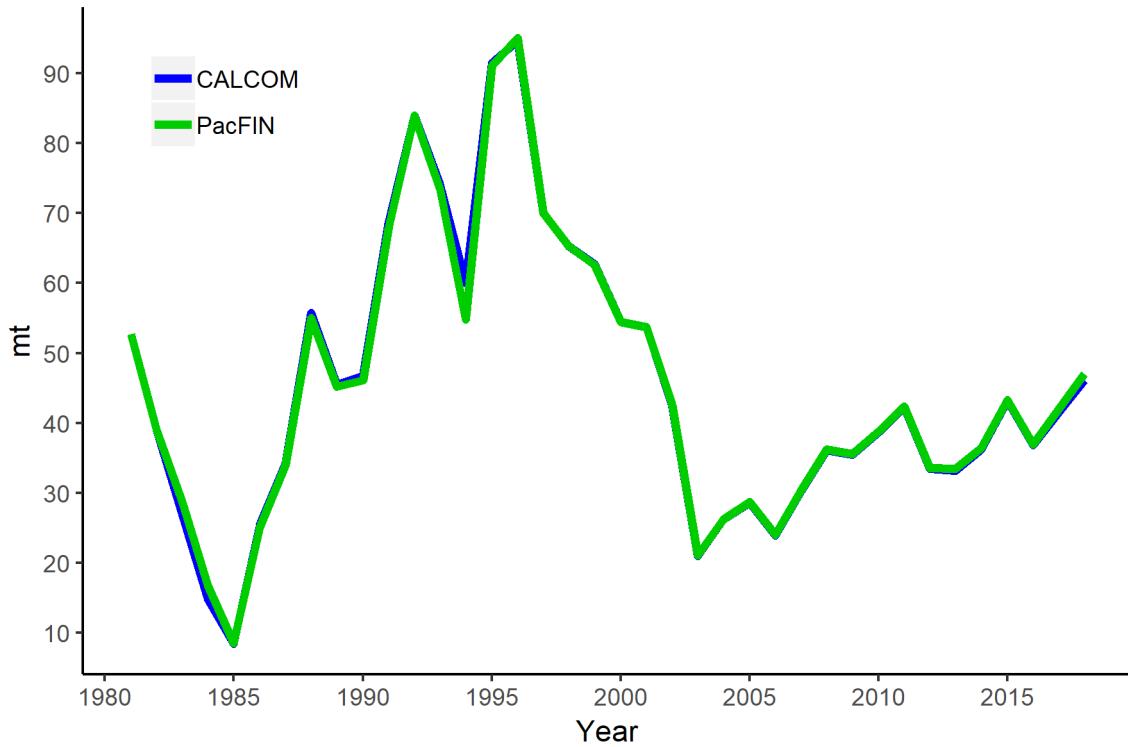

Figure 7: Commercial landings estimates from CALCOM add PacFIN.

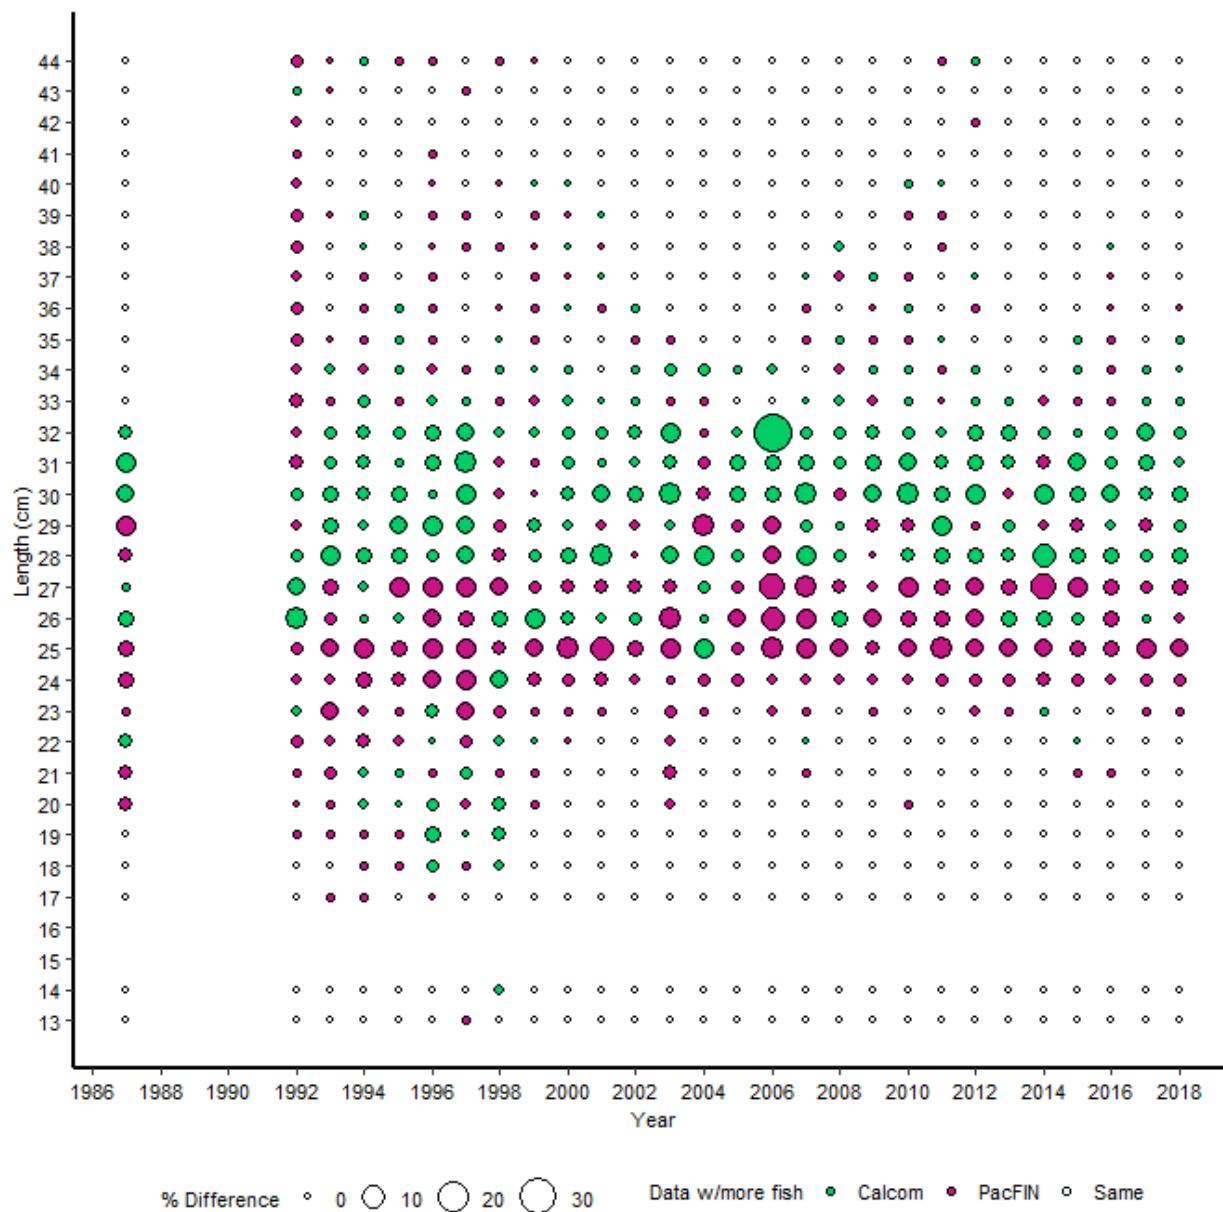

Figure 8: Percent differences in the expanded length compositions by year from CALCOM and PacFIN. The same market categories were used for each dataset, but each database was subject to further independent filtering criteria and expansion algorithms.

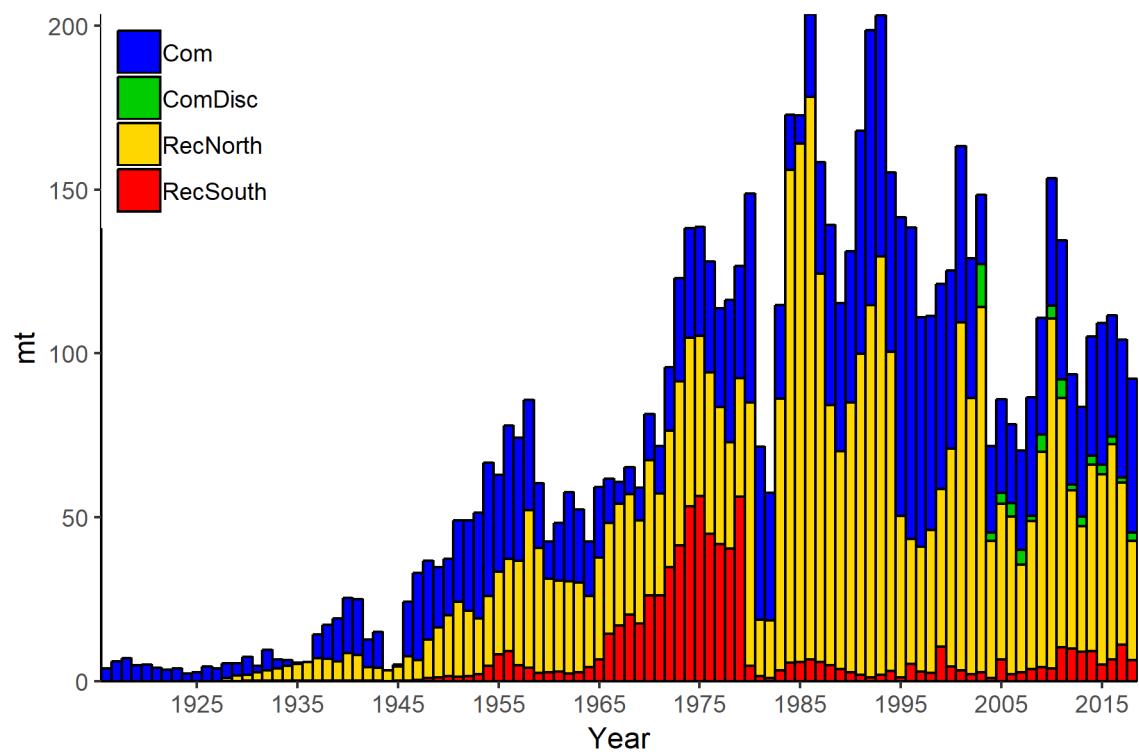

Figure 9: Commercial and recreational landings estimates prior to any data modification or interpolation to the recreational catches or hindcasting of commercial discards.

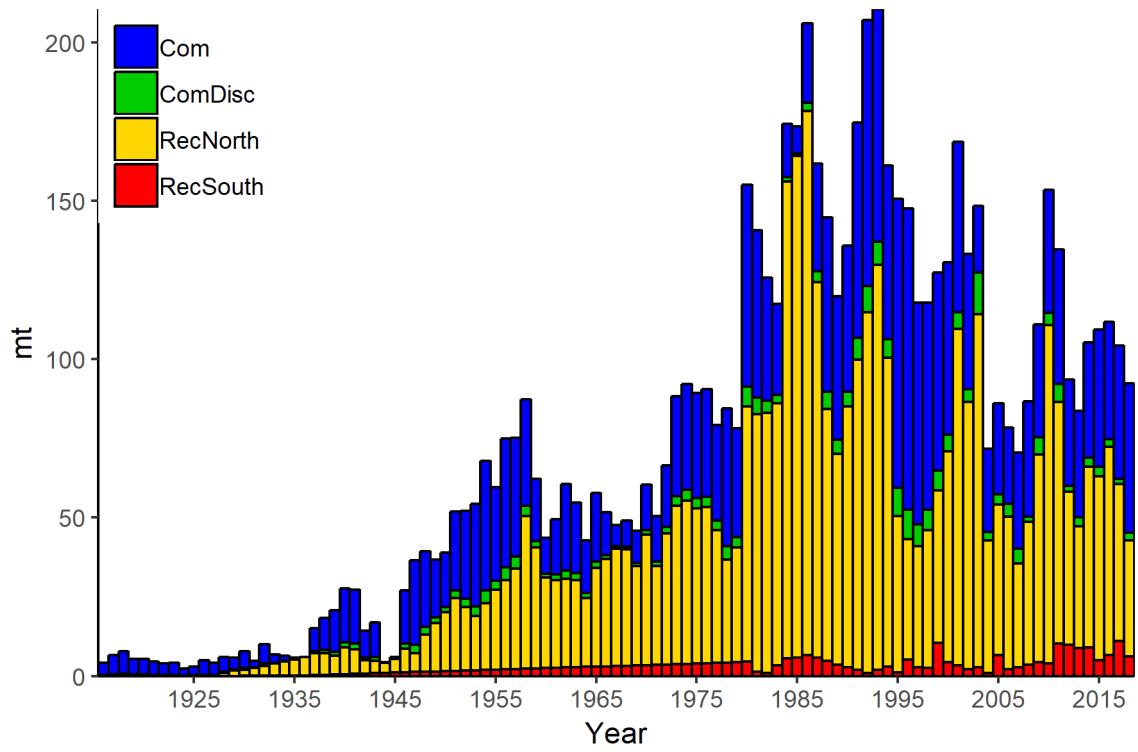

Figure 10: Commercial and recreational landings estimates after data modification and interpolations were made to the recreational catches and commercial discards.

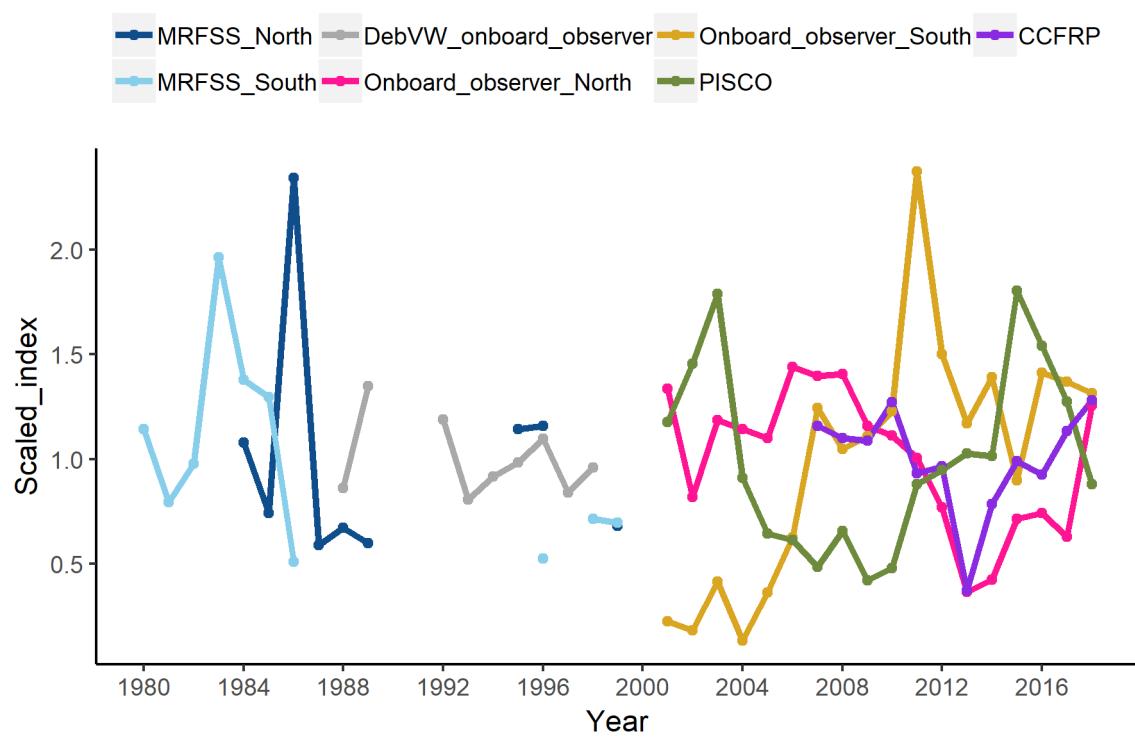

Figure 11: Comparison of all indices of abundance (scaled to their means).

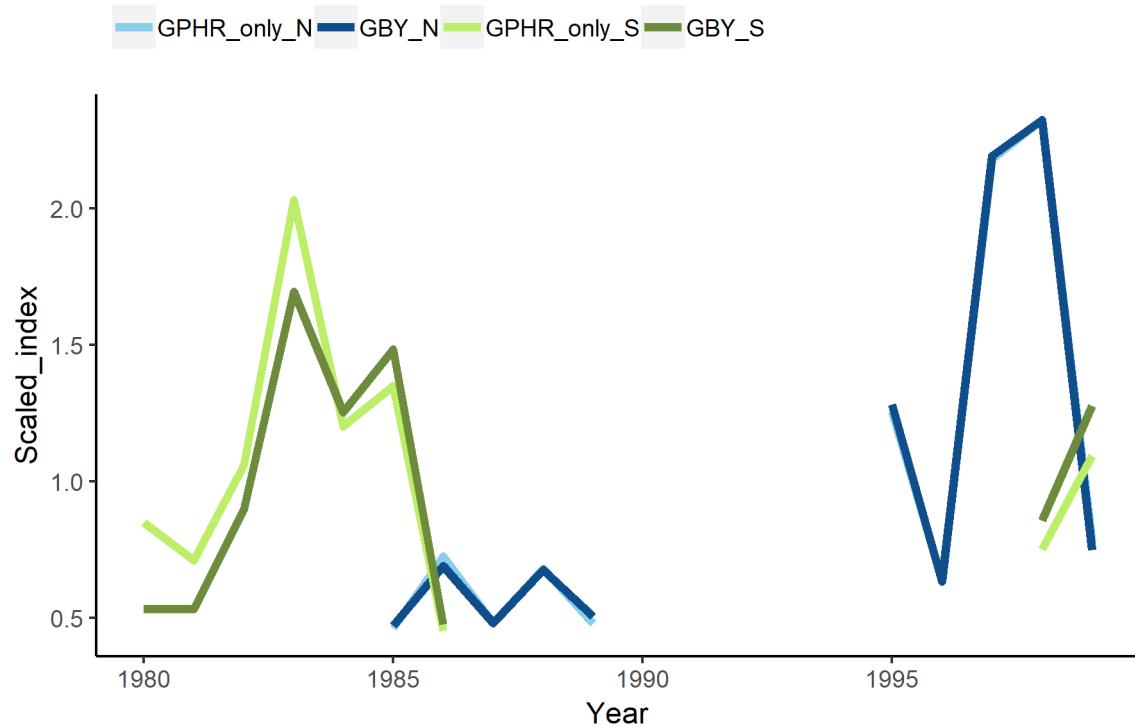

Figure 12: Comparison of indices of abundance (scaled to their means) for the MRFSS dockside CPFV survey between a gopher-only and GBYR complex index for north and south of Point Conception.

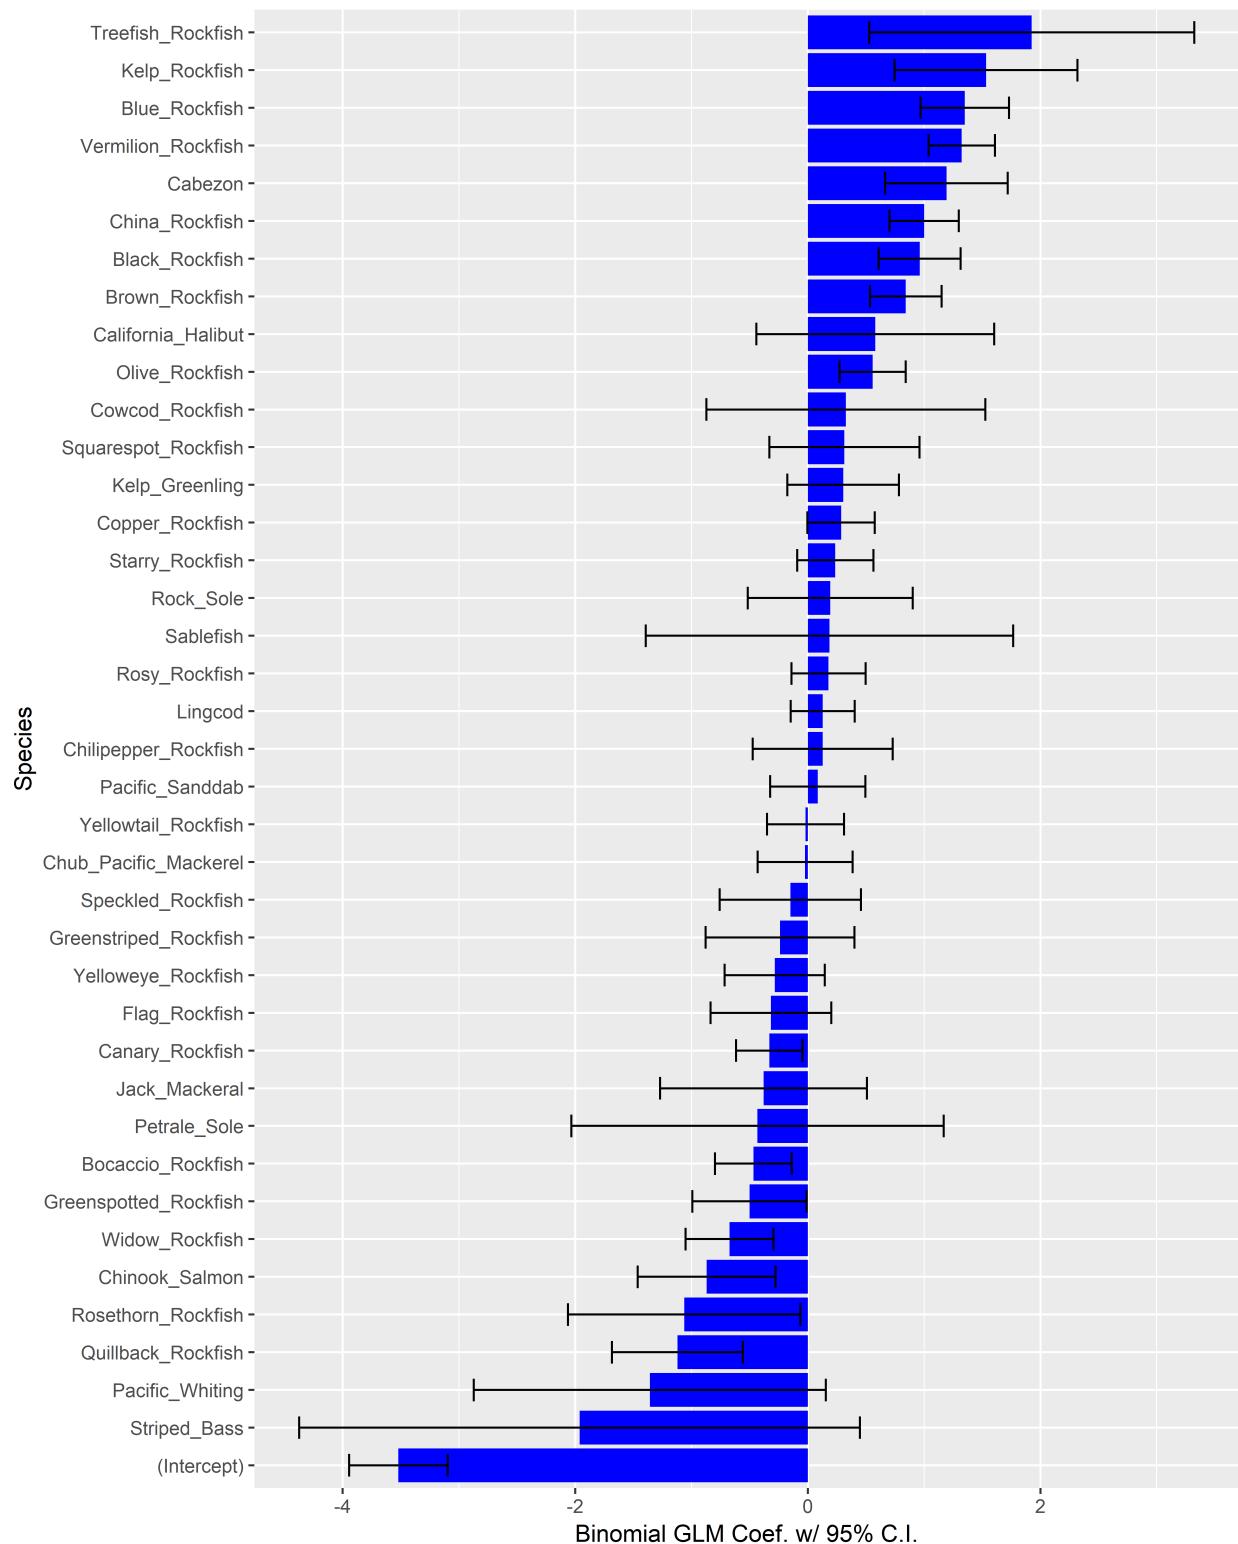

Figure 13: Species coefficients from the binomial GLM for presence/absence of GBYR in the Marine Recreational Fisheries Statistics Survey (MRFSS) CPFV mode dockside survey data set north of Point Conception. Horizontal bars are 95% confidence intervals.

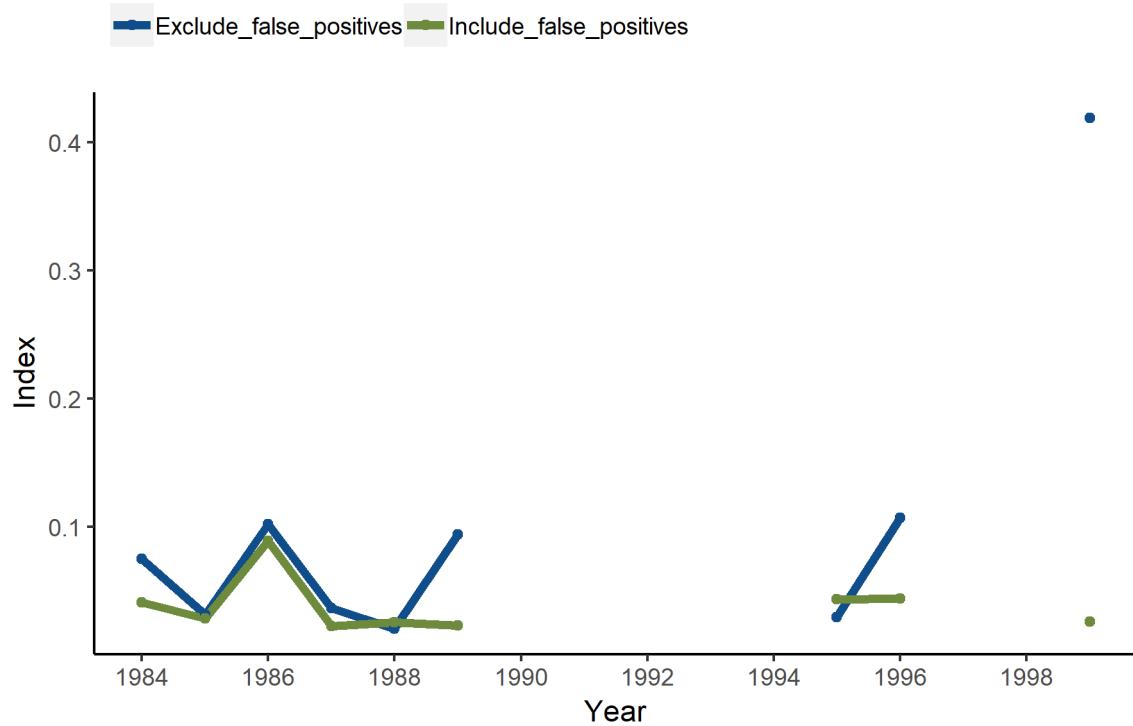

Figure 14: Comparisons of the indices of abundance for GBYR north of Point Conception from the MRFSS dockside CPVS survey that either include or exclude the trips identified as false positives from the Stephens-MacCall filter.

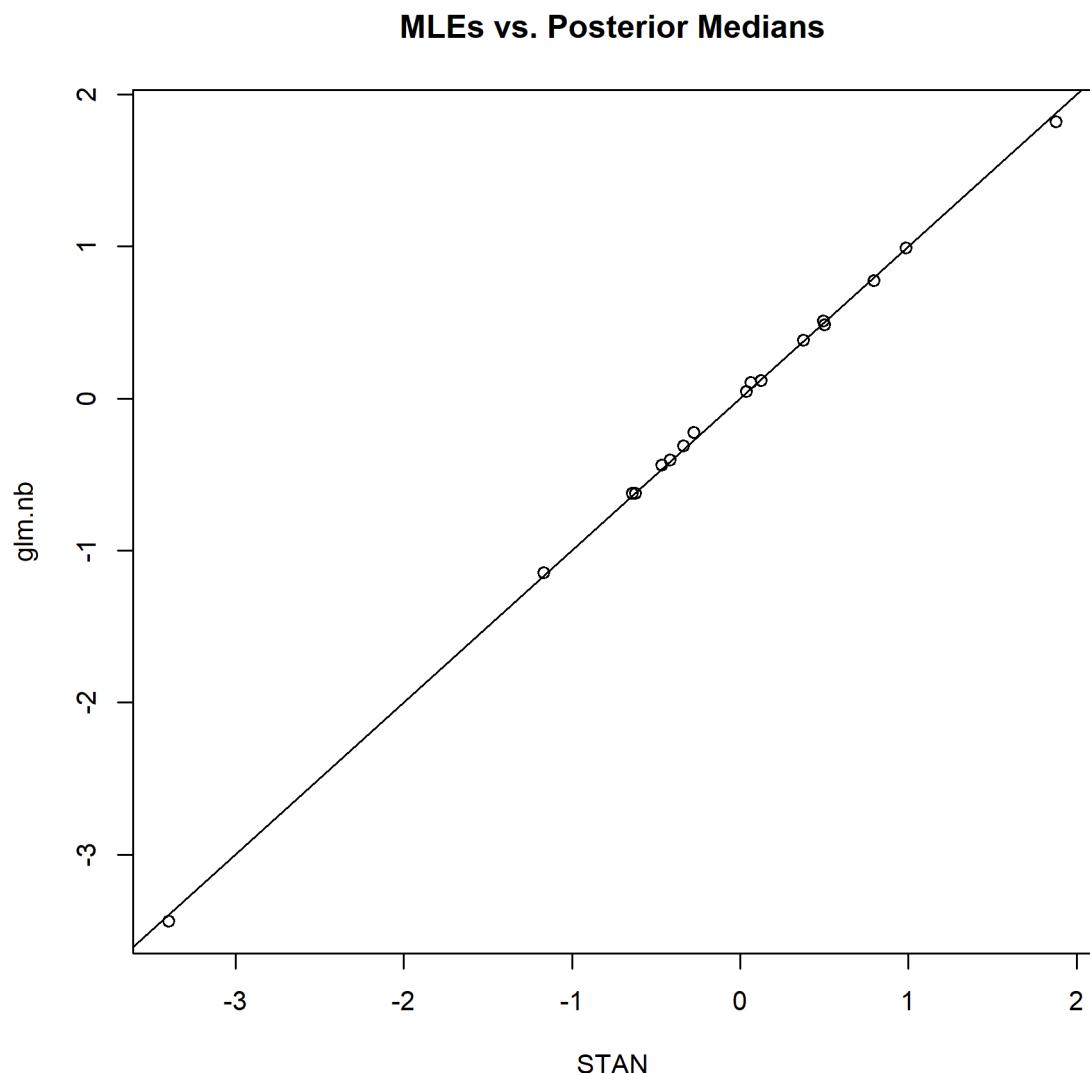

Figure 15: Comparison of negative binomial predictions (CPUE) to observed means in each stratum (year) MRFSS CPFV dockside index north of Point Conception. The 1:1 plot is for reference.

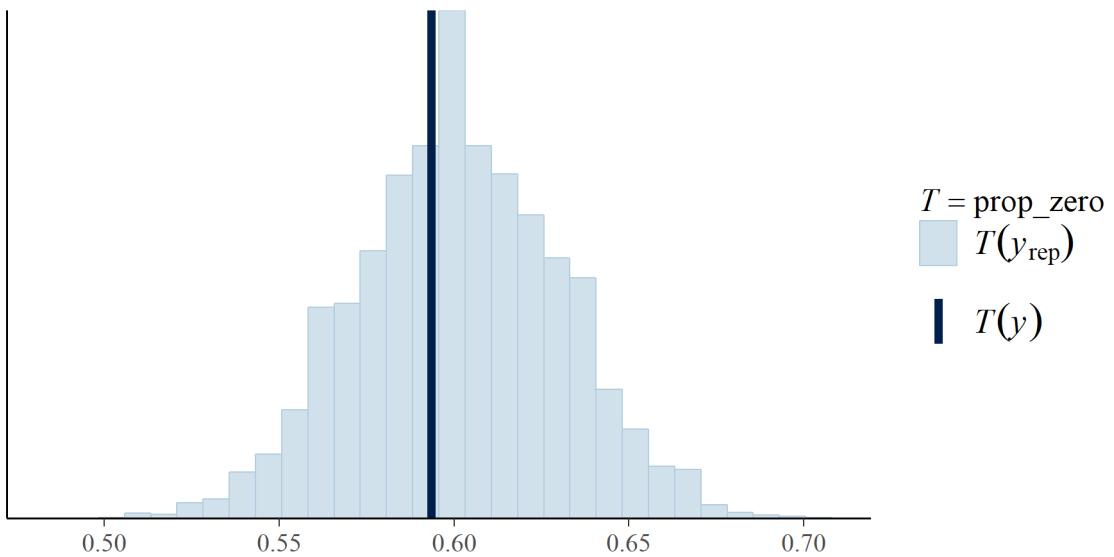

Figure 16: Posterior predictive distribution of the proportion of zero observations in replicate data sets generated by the negative binomial model for MRFSS dockside CPFV index north of Point Conception.

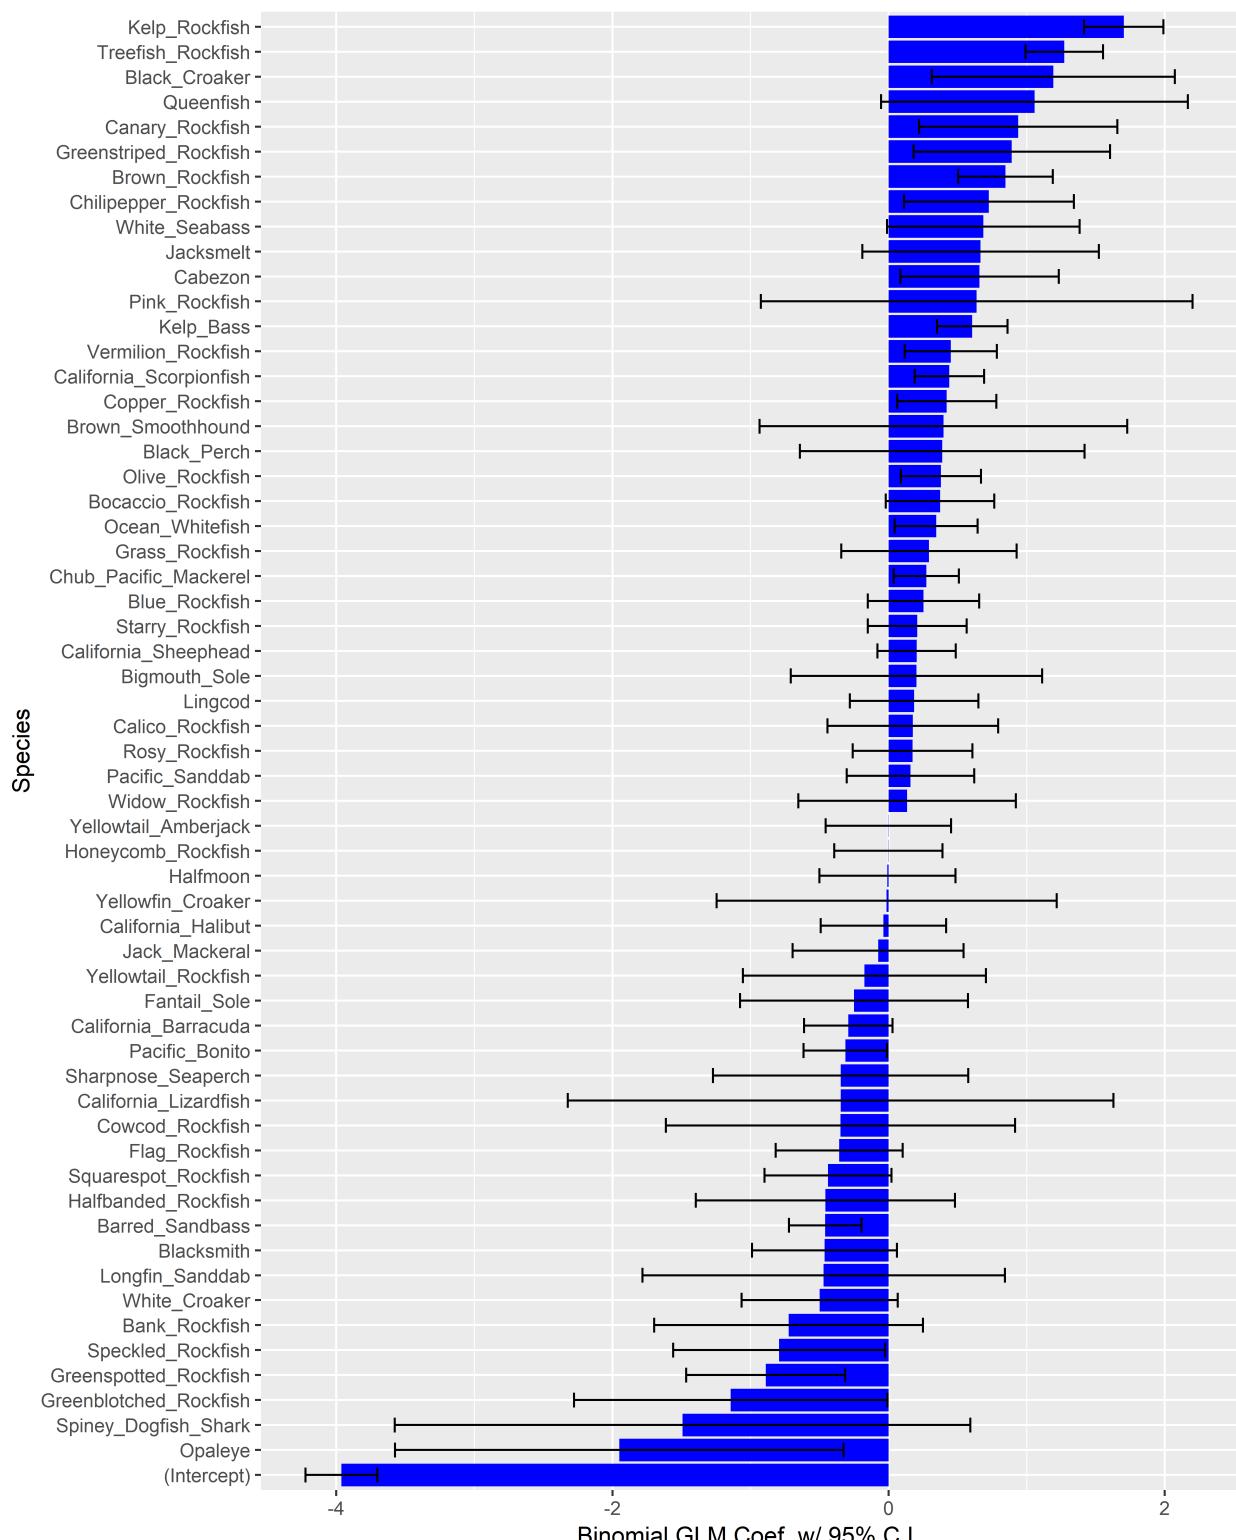

Figure 17: Species coefficients from the binomial GLM for presence/absence of GBYR in the Marine Recreational Fisheries Statistics Survey (MRFSS) CPFV mode dockside survey data set north of Point Conception. Horizontal bars are 95% confidence intervals.

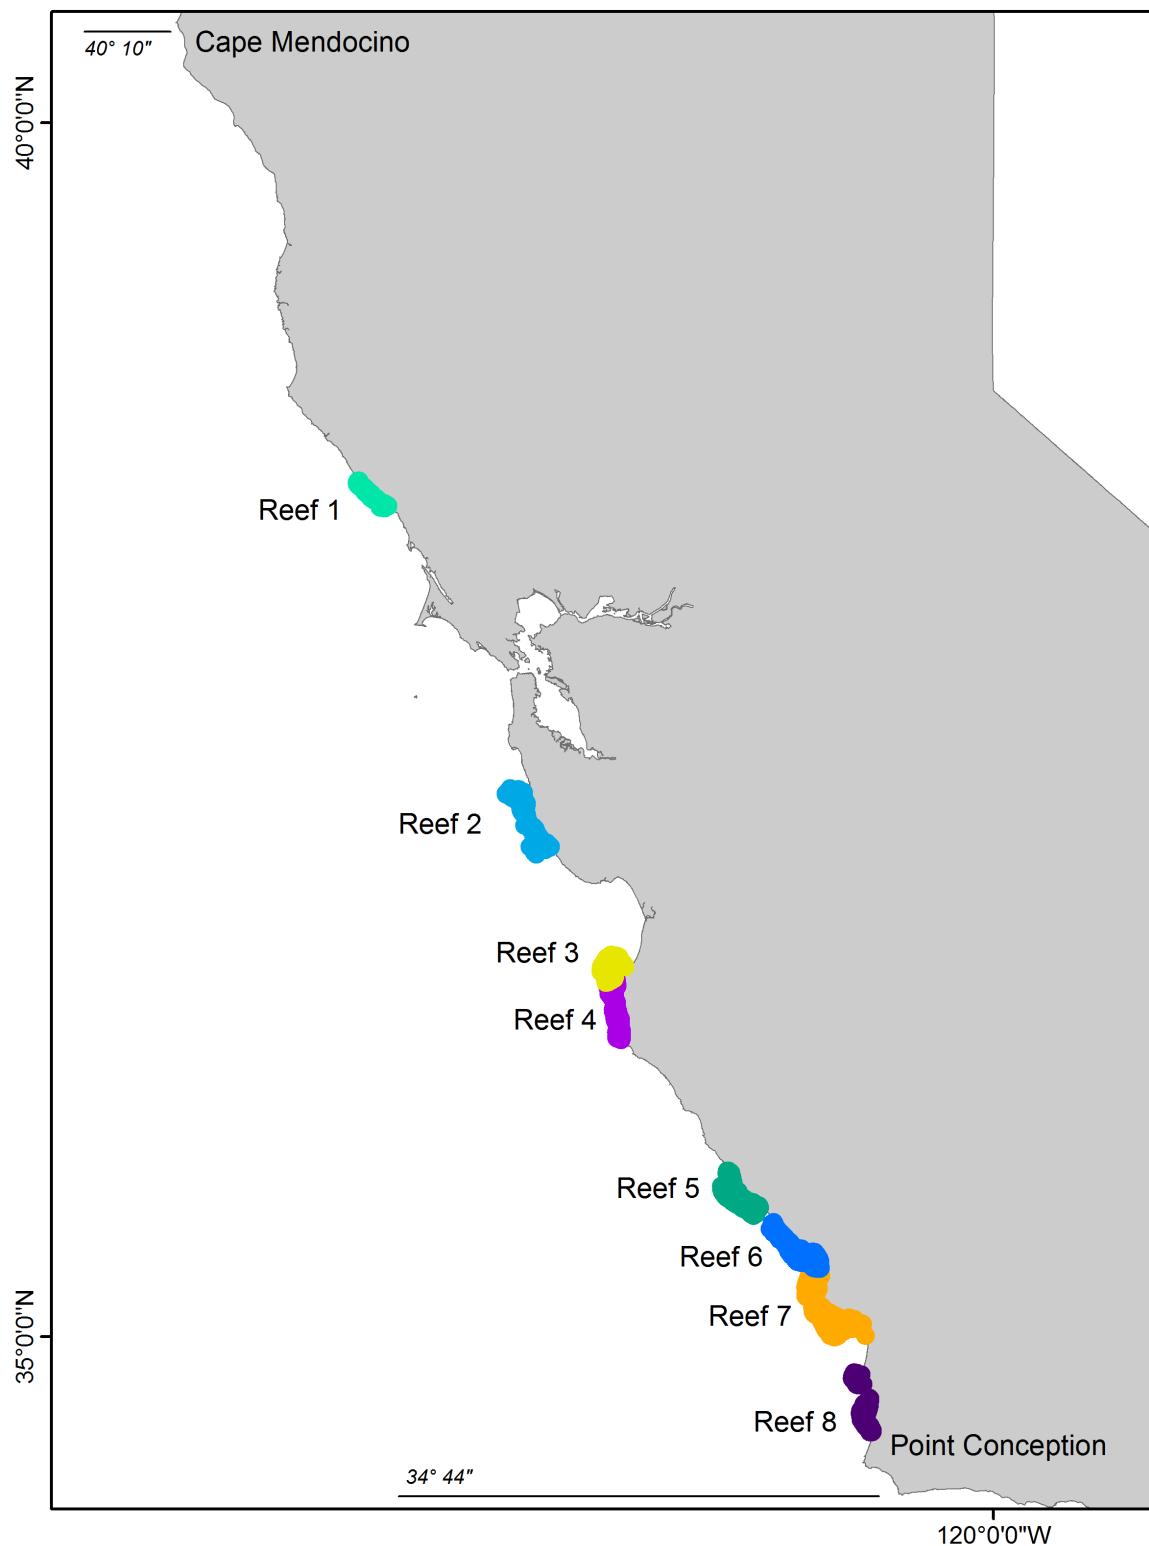

Figure 18: Map of the reefs used in the Deb Wilson-Vandenbervy CPFV onboard observer survey index of abundance.

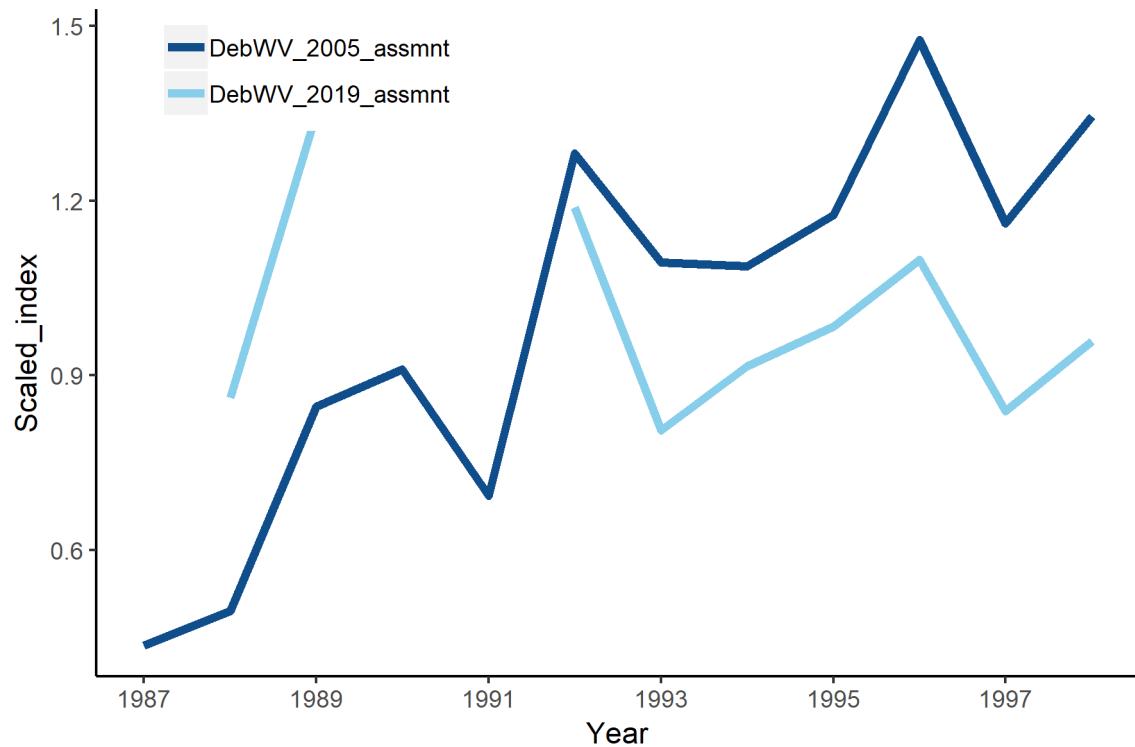

Figure 19: Comparison of the index developed for the Deb Wilson-Vandenberg CPFV on-board observer survey from the 2005 assessment and for the 2019 assessment.

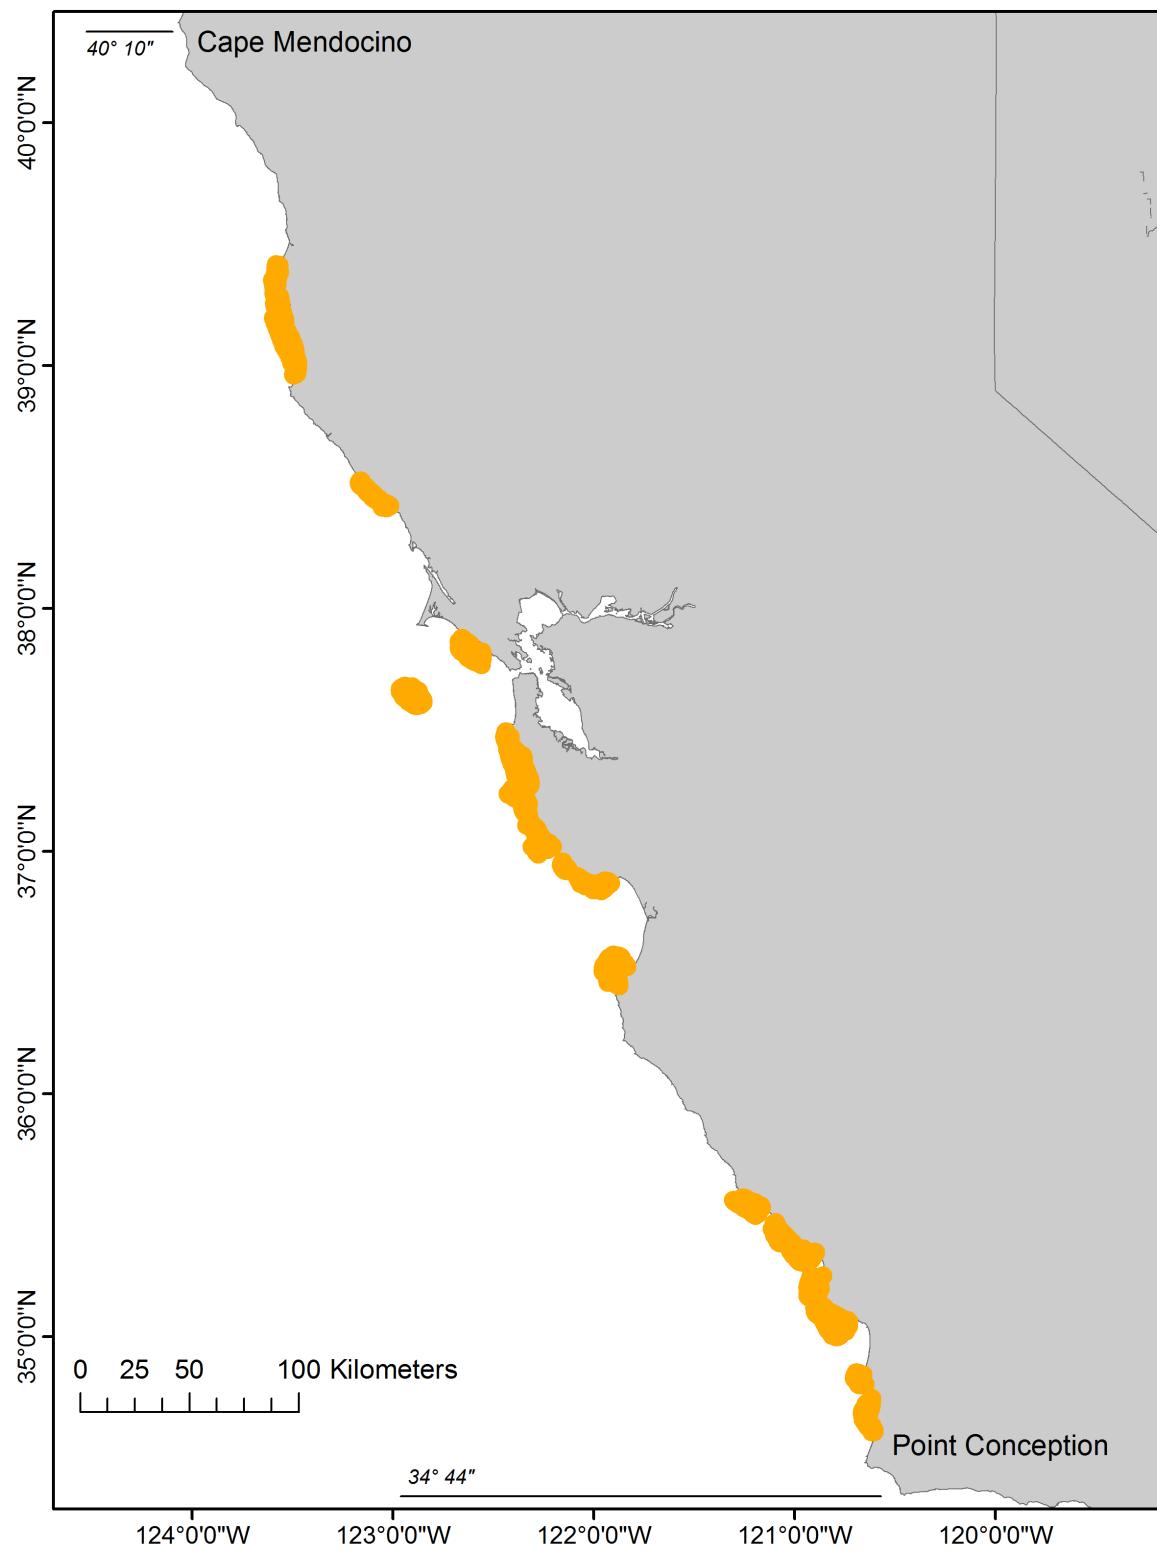

Figure 20: Map of the reefs selected for the final index for the onboard observer surveys (CDFW and Cal Poly) north of Point Conception

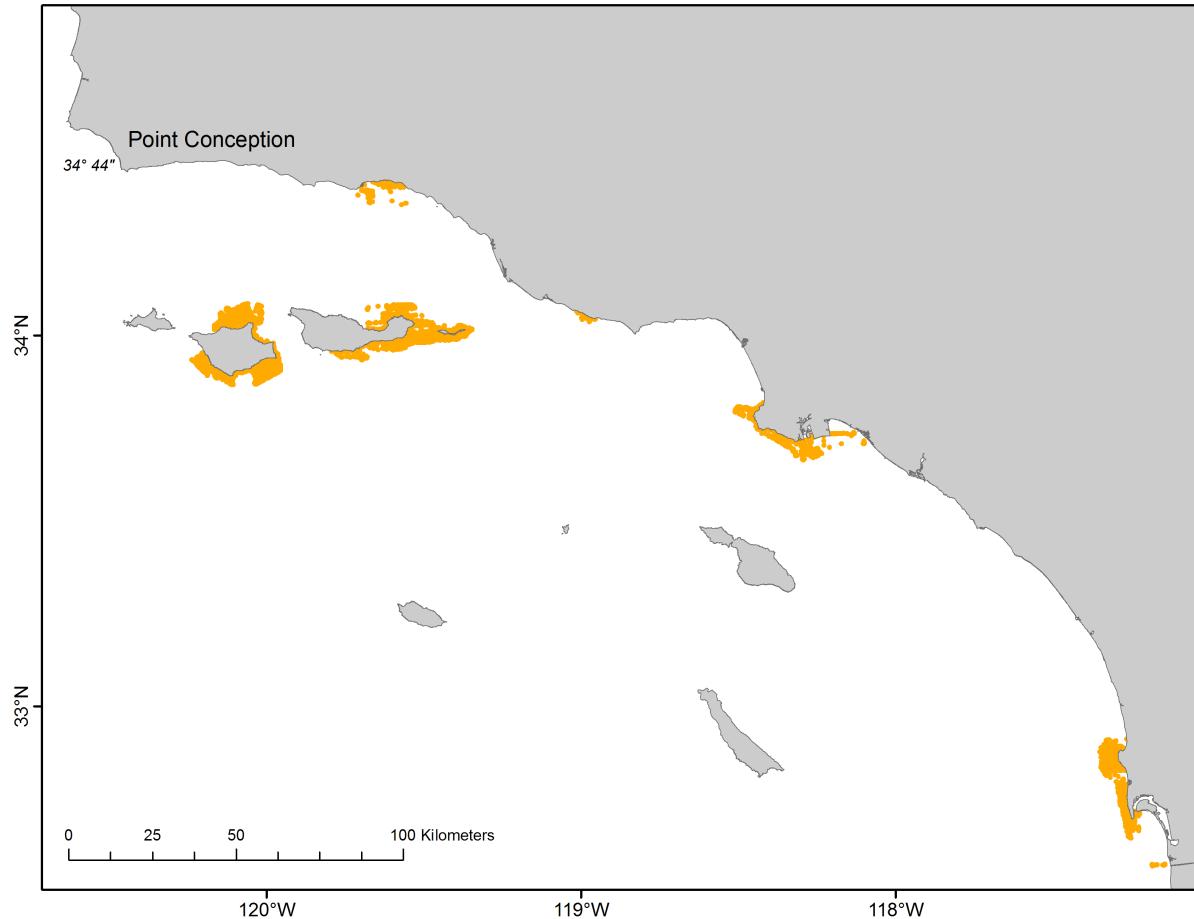

Figure 21: Map of the reefs selected for the final index for the CDFW onboard observer survey south of Point Conception

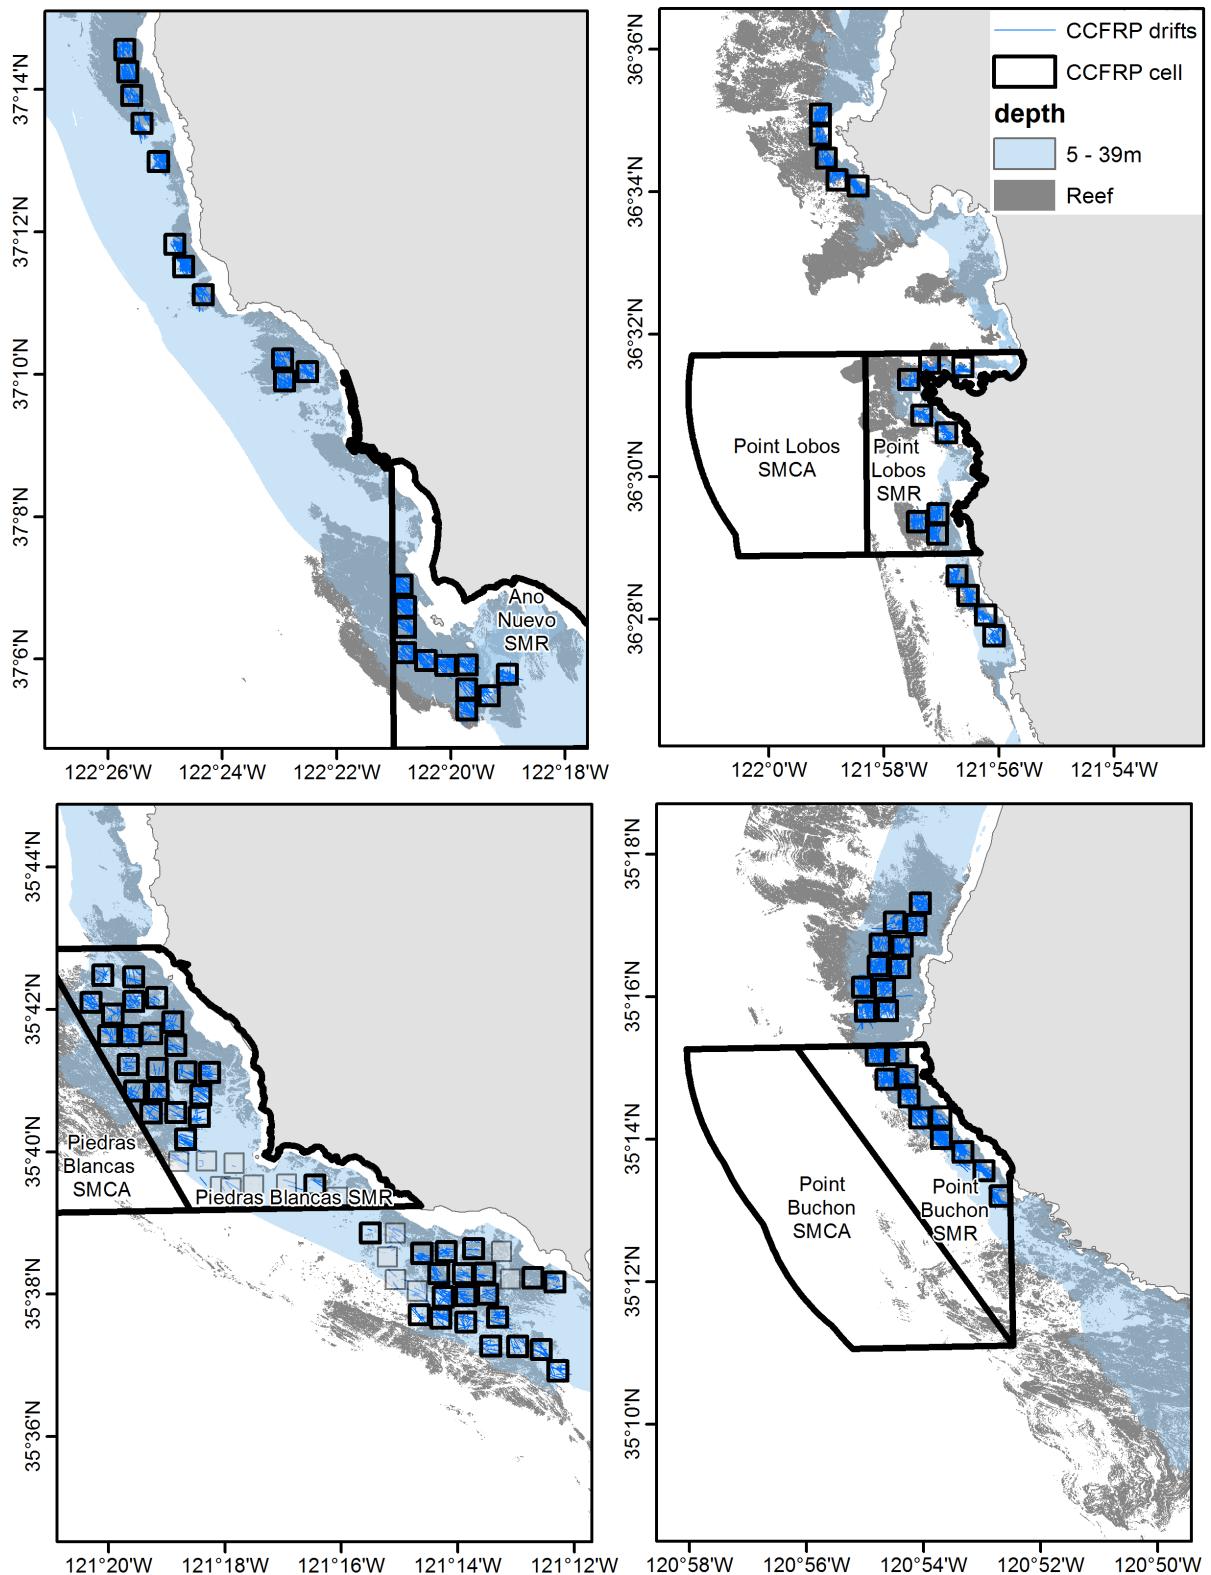

Figure 22: Map of the four MPAs sample consistently through time for the CCFRP fishery-independent survey.

MLEs vs. Posterior Medians

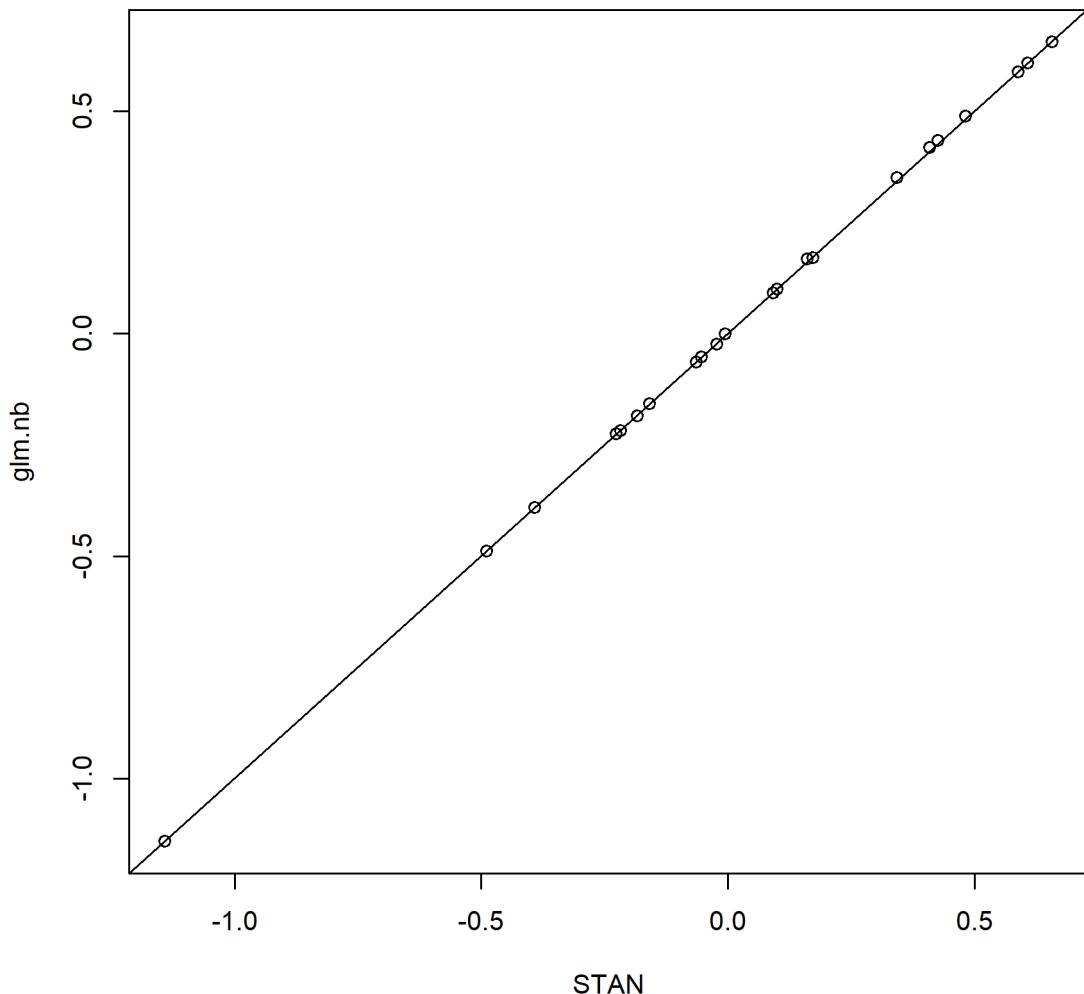

Figure 23: Comparison of negative binomial predictions (CPUE) to observed means in each stratum (year) for the CCFRP index. The 1:1 plot is for reference.

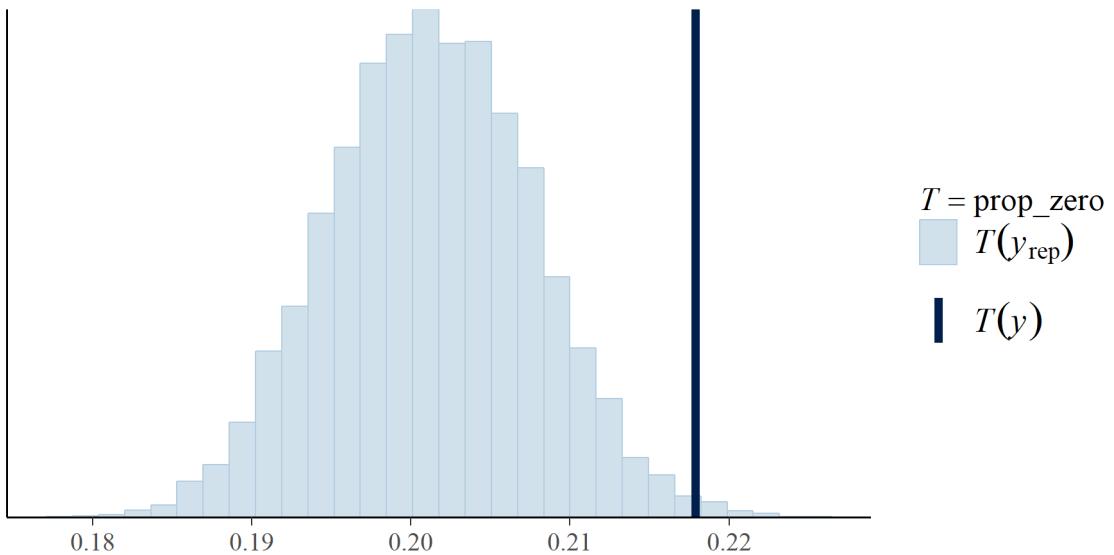

Figure 24: Posterior predictive distribution of the proportion of zero observations in replicate data sets generated by the negative binomial model for the CCFRP index.

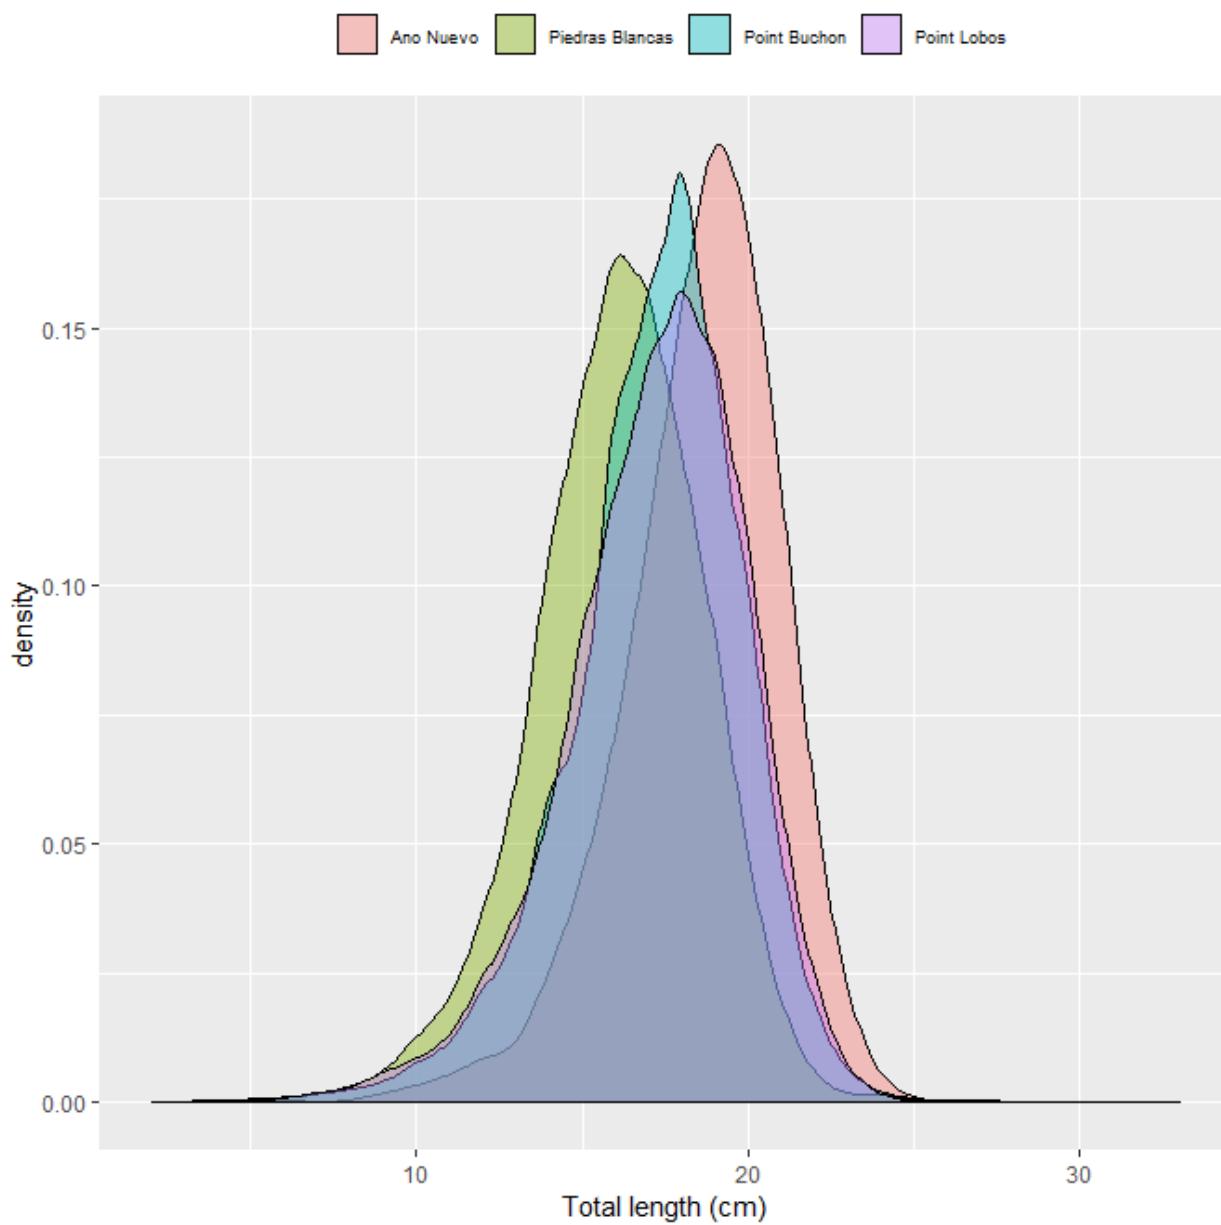

Figure 25: Length distributions of GBYR for the four MPAs sampled by the CCFRP survey used in this assessment.

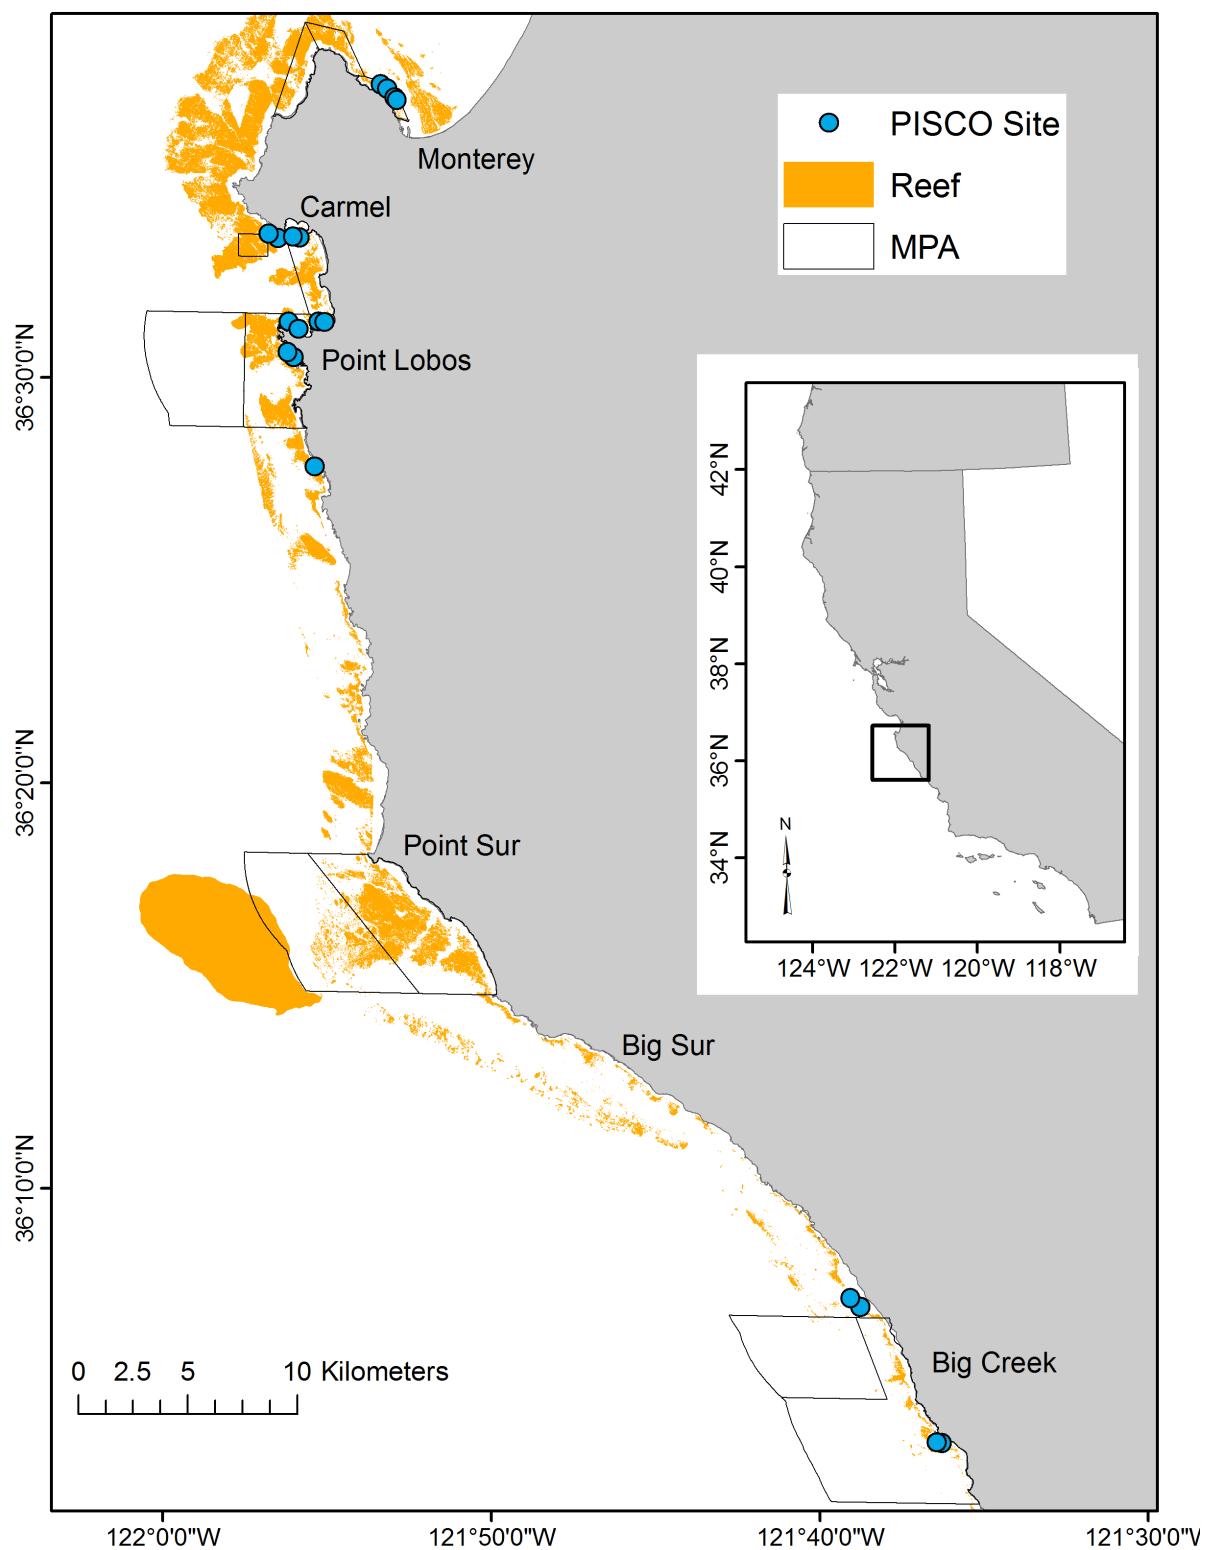

Figure 26: Map of the sites sampled consistently through time for the PISCO kelp forest fish survey.

MLEs vs. Posterior Medians

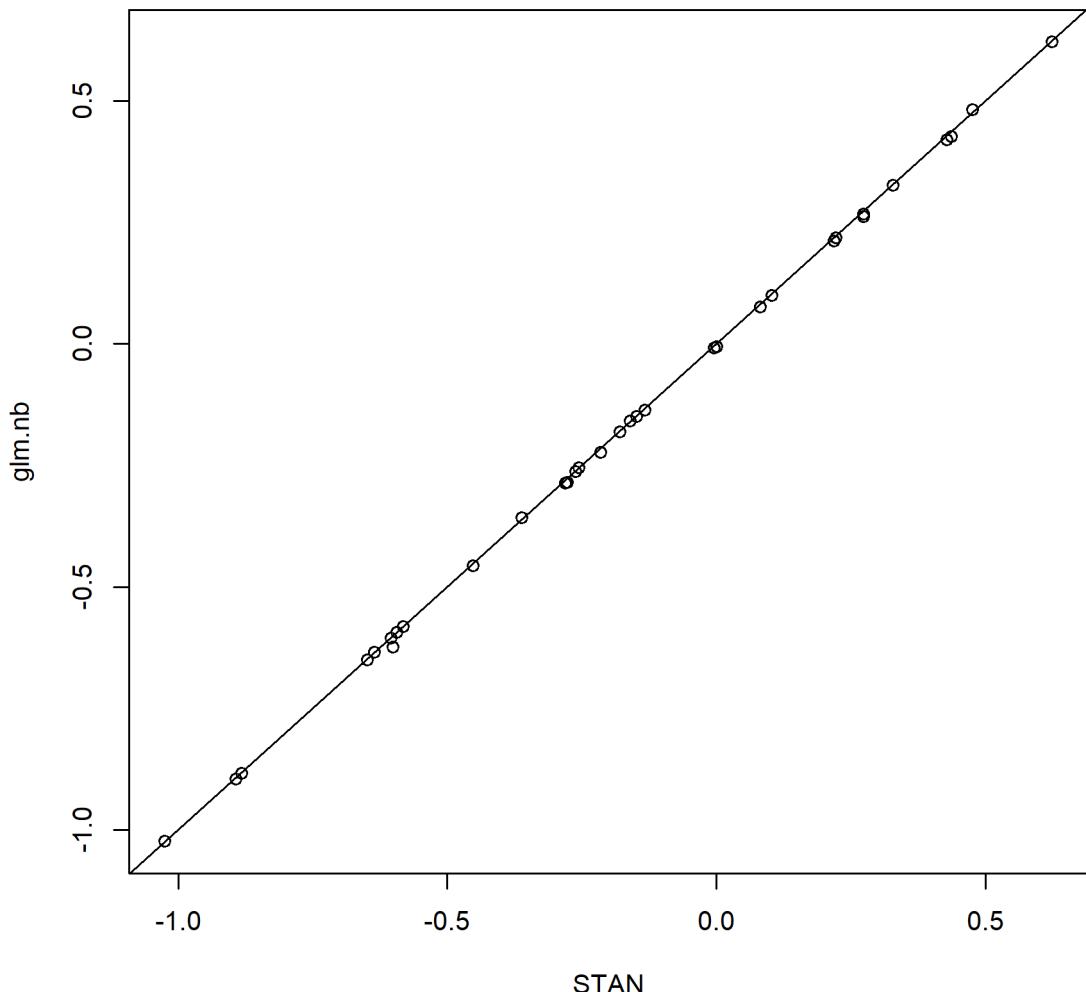

Figure 27: Comparison of negative binomial predictions (CPUE) to observed means in each stratum (year) for the PISCO kelp forest fish survey index. The 1:1 plot is for reference.

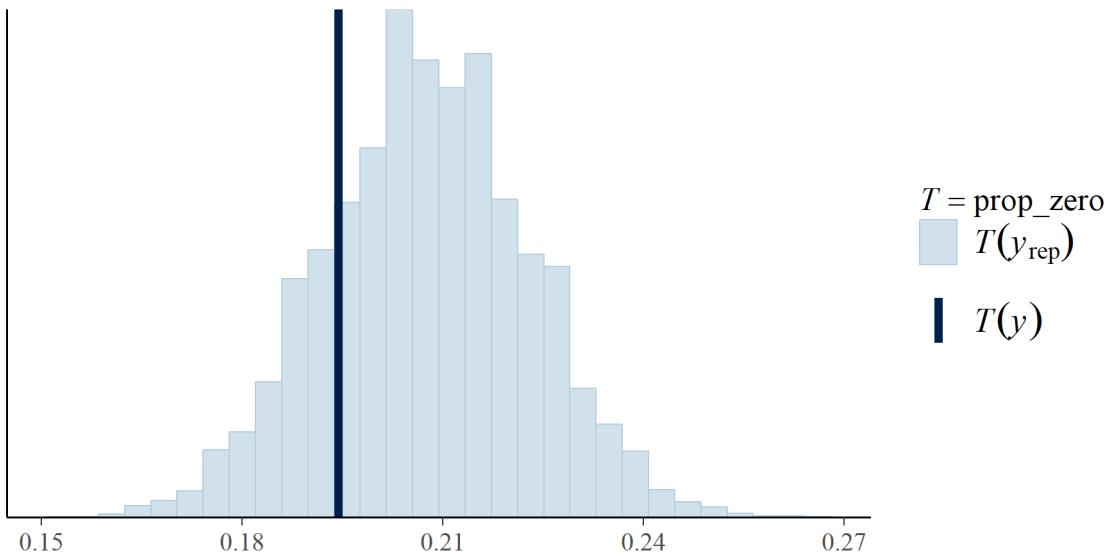

Figure 28: Posterior predictive distribution of the proportion of zero observations in replicate data sets generated by the negative binomial model for the PISCO kelp forest fish survey.

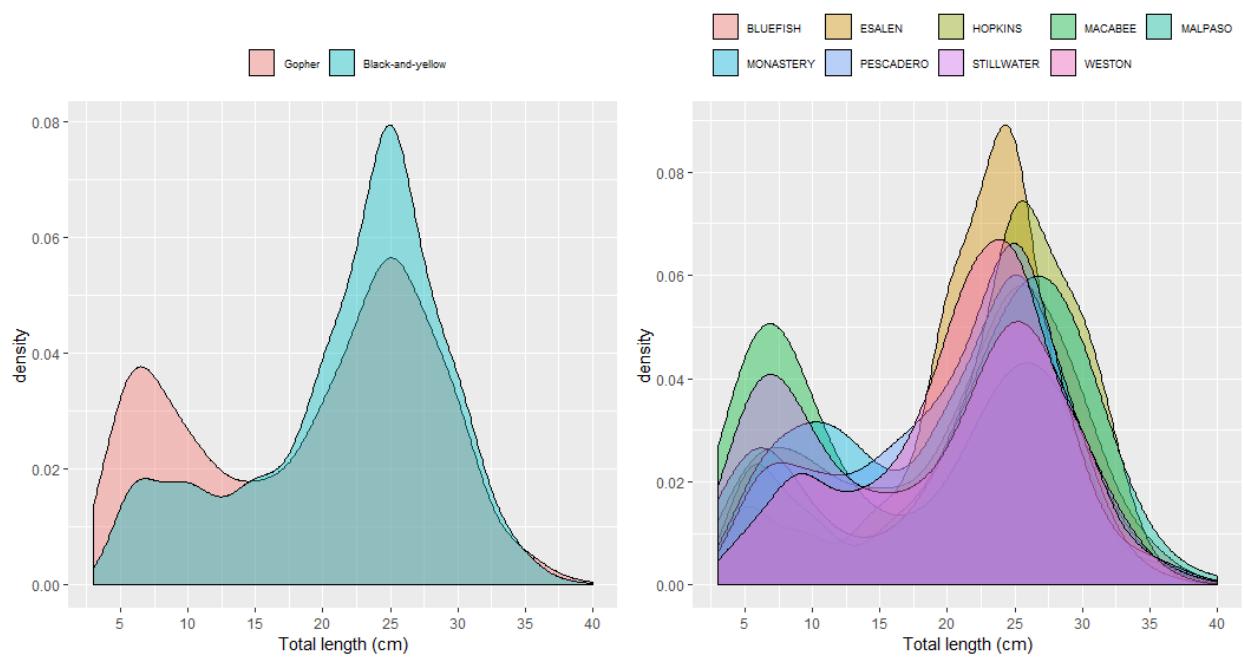

Figure 29: Plots of the length distributions from the PISCO kelp forest fish survey by species (left) and for combined species by site (right) for sites included in the final index of abundance.

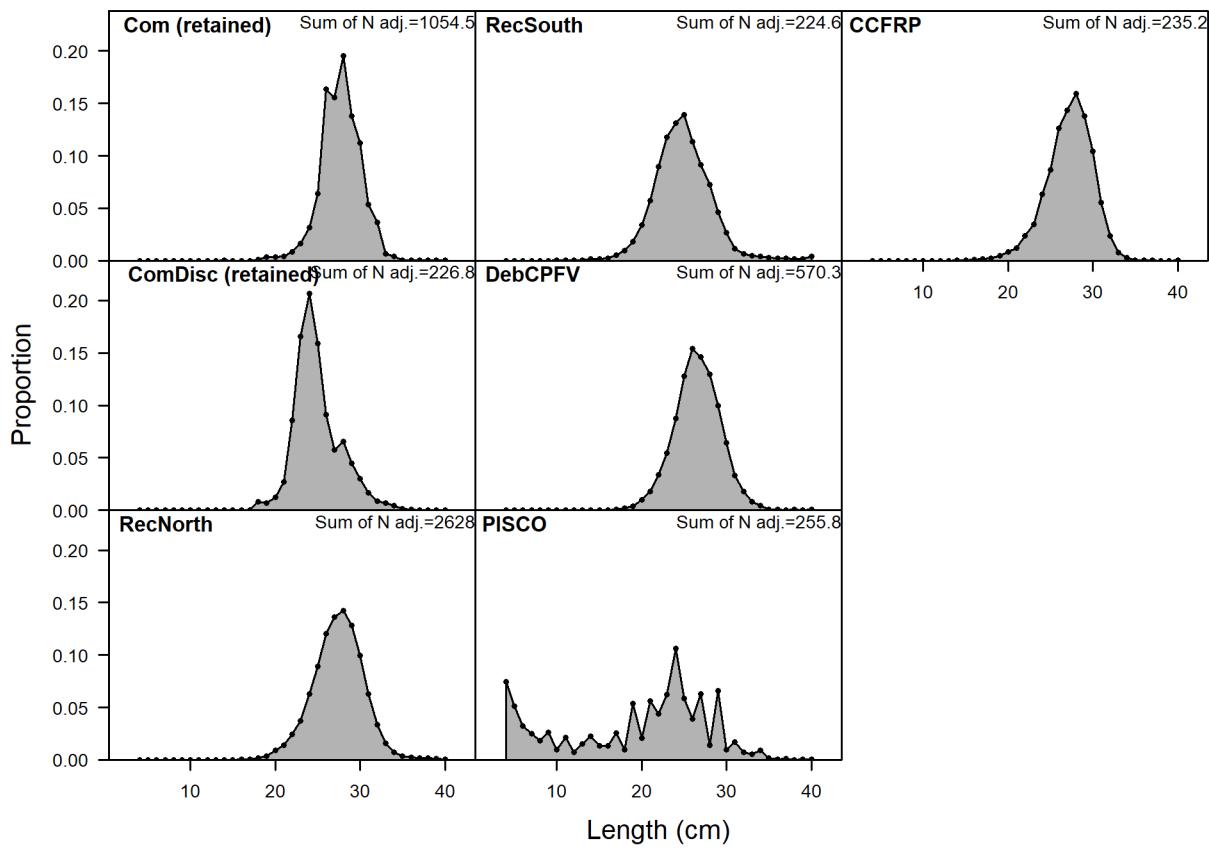

Figure 30: Length comp data, aggregated across time by fleet. Labels ‘retained’ and ‘discard’ indicate discarded or retained sampled for each fleet. Panels without this designation represent the whole catch.

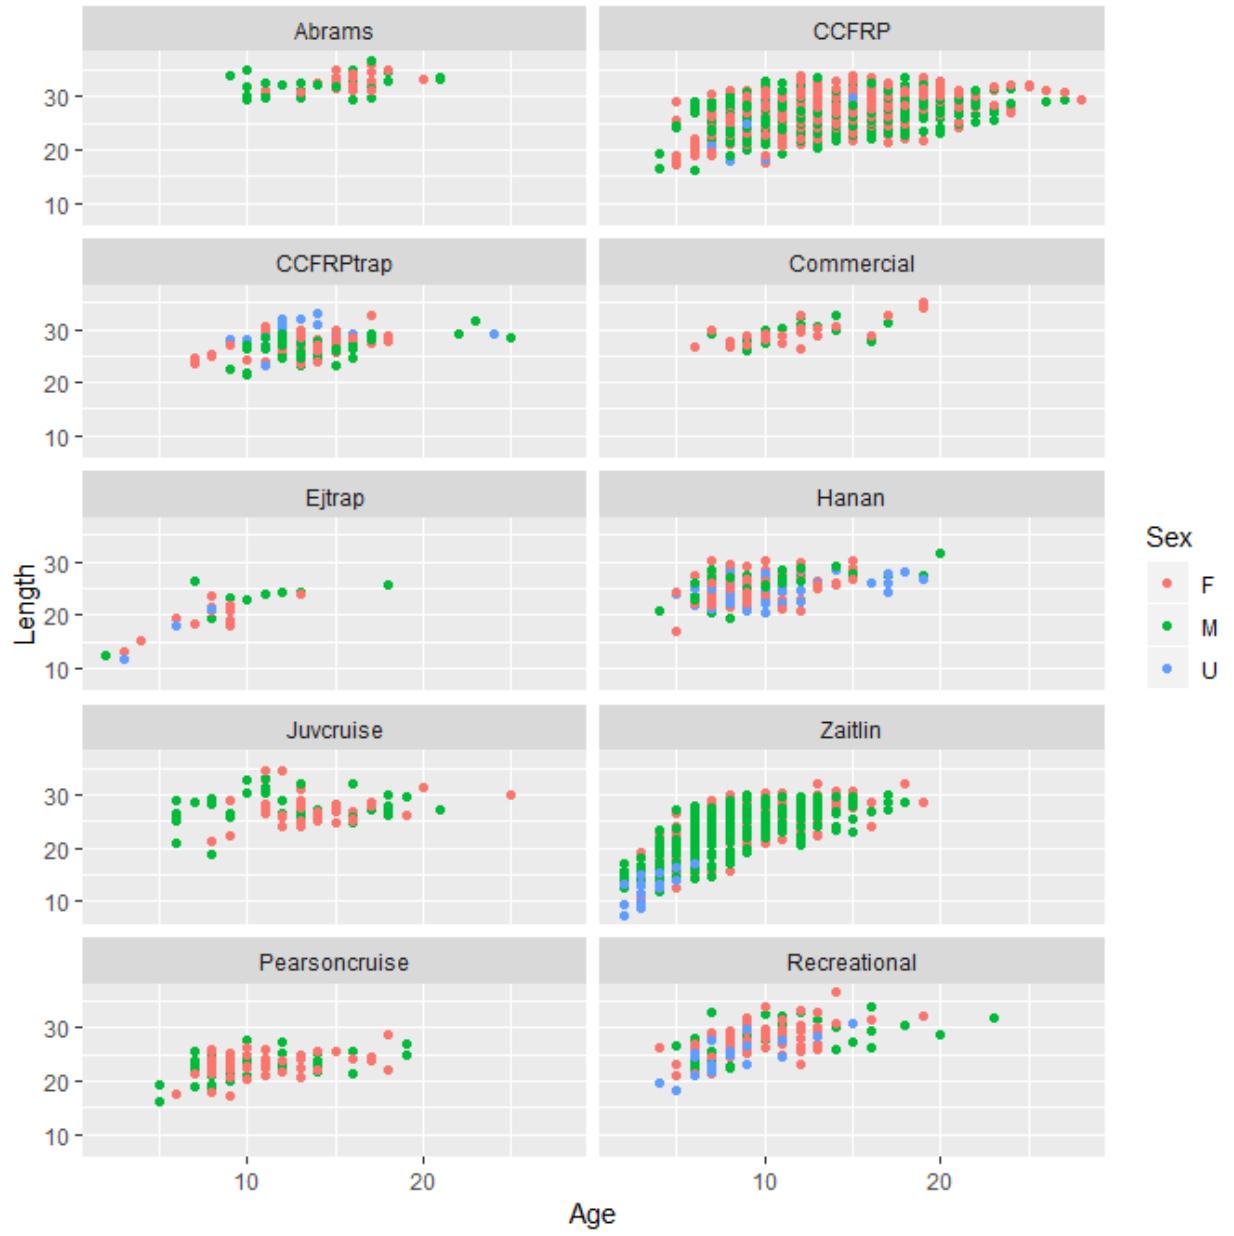

Figure 31: Available length-at-age data for gopher and black-and-yellow rockfish by sex and data source. The Zaitlin study is all black-and-yellow rockfish. The remaining plots represent gopher rockfish

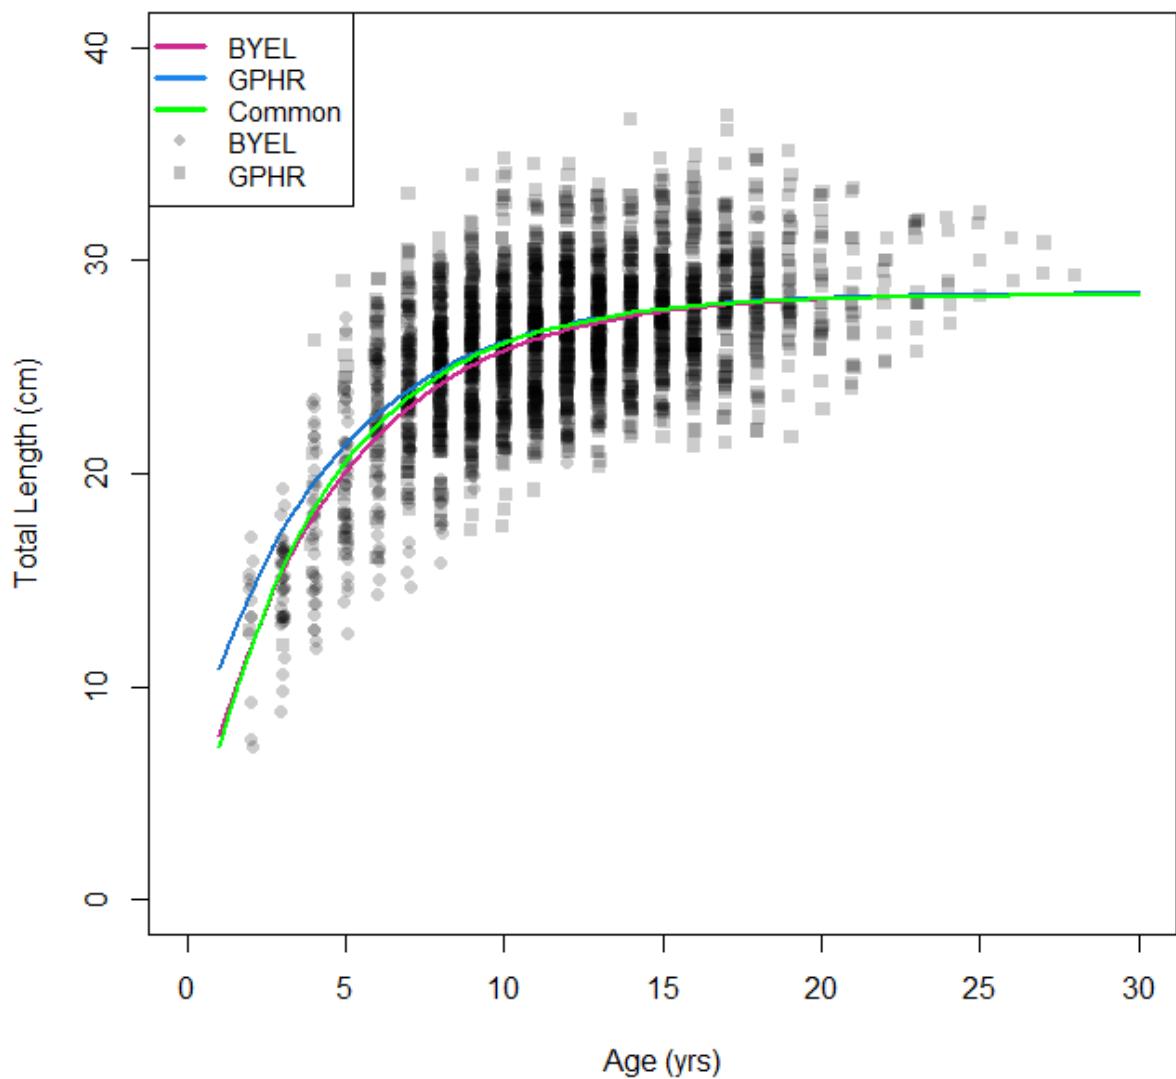

Figure 32: External estimates of growth for gopher and black-and-yellow rockfish from fits to von Bertalanffy growth models.

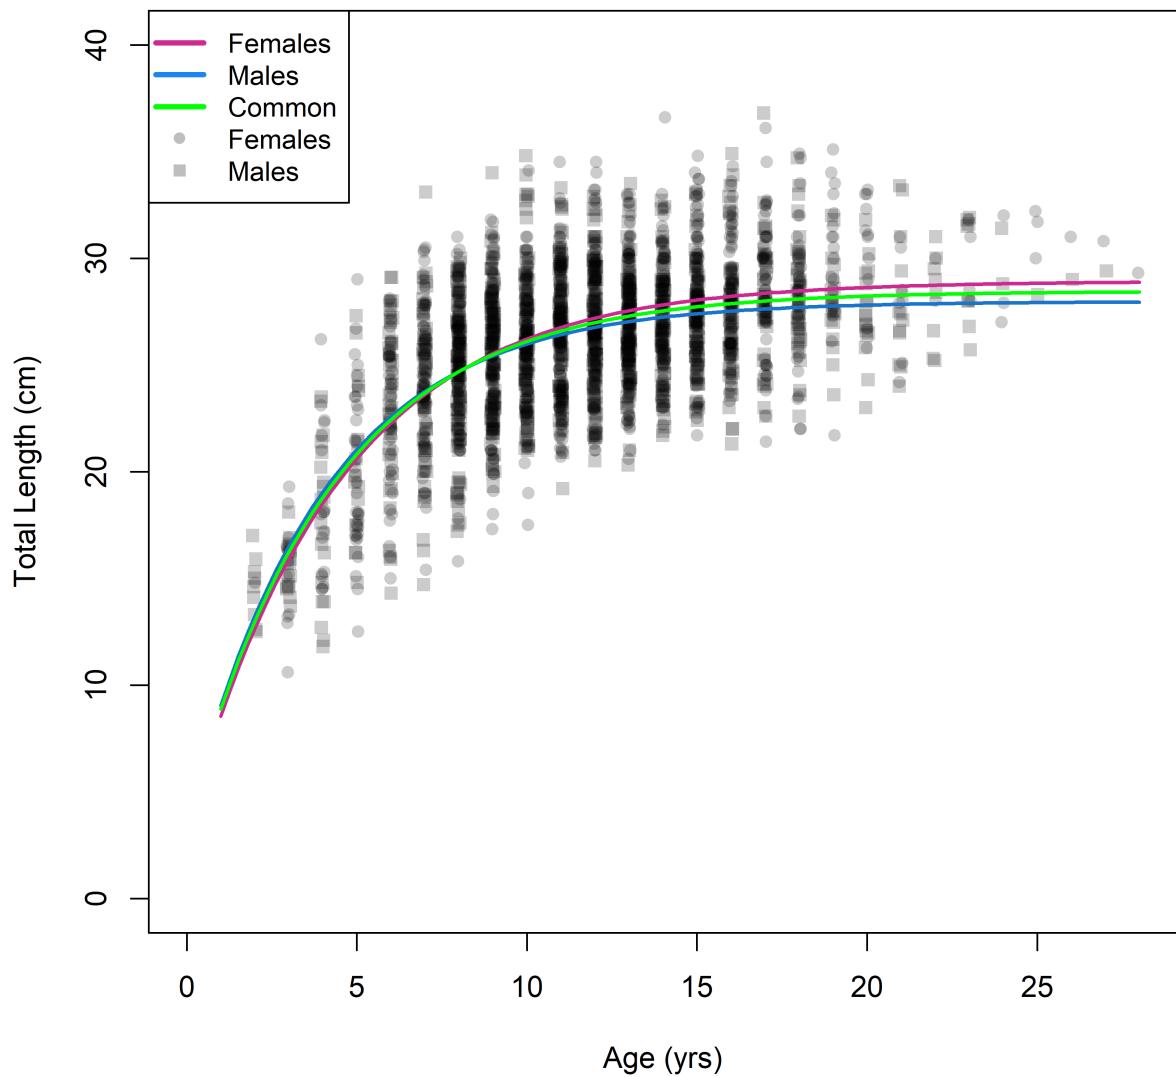

Figure 33: External estimates of growth for GBYR combined by sex from fits to von Bertalanffy growth models.

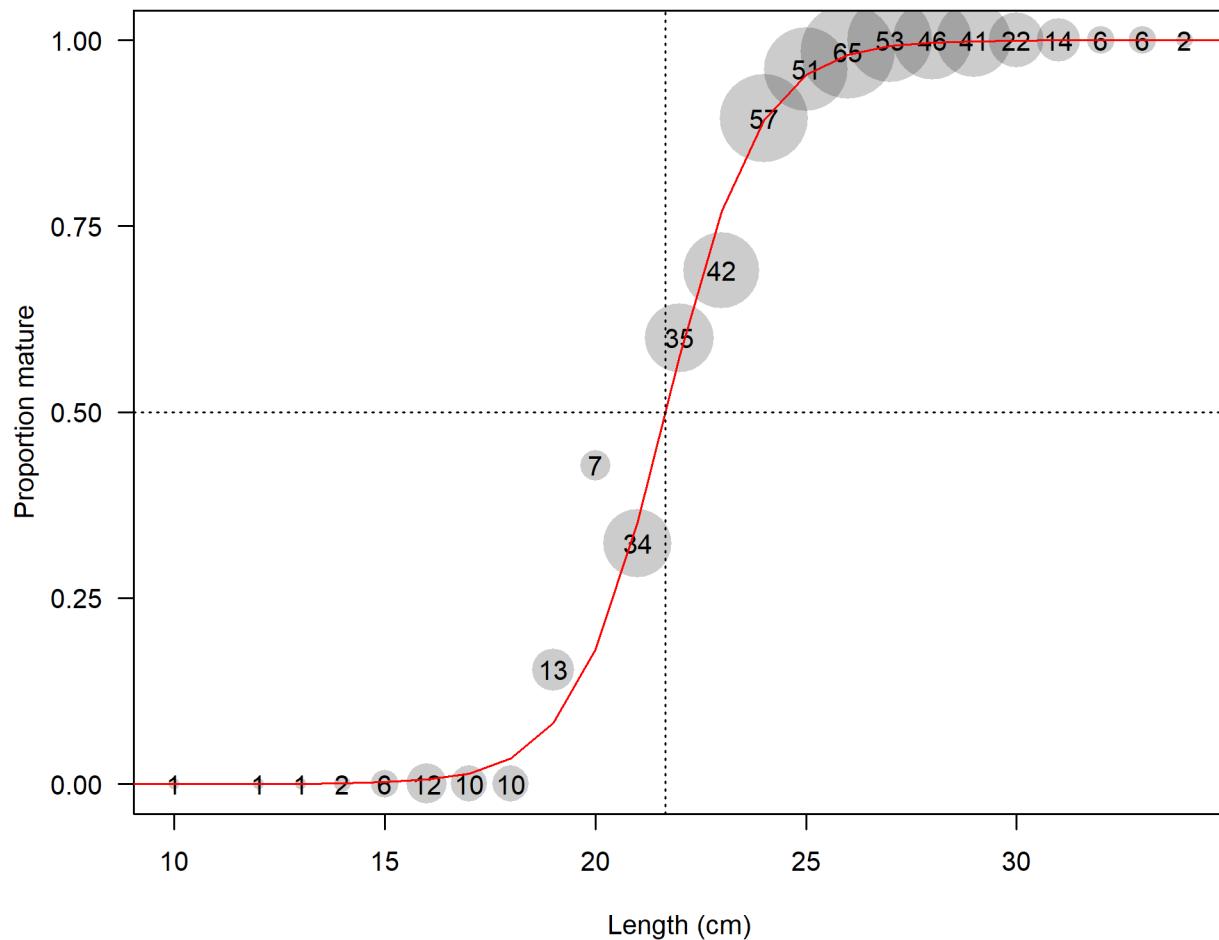

Figure 34: Maturity ogive for females estimated from black-and-yellow rockfish from Zaitlin (1986) and gopher rockfish from Meyers-Cherry (2014). Sample sizes at a given length are shown in the circles.

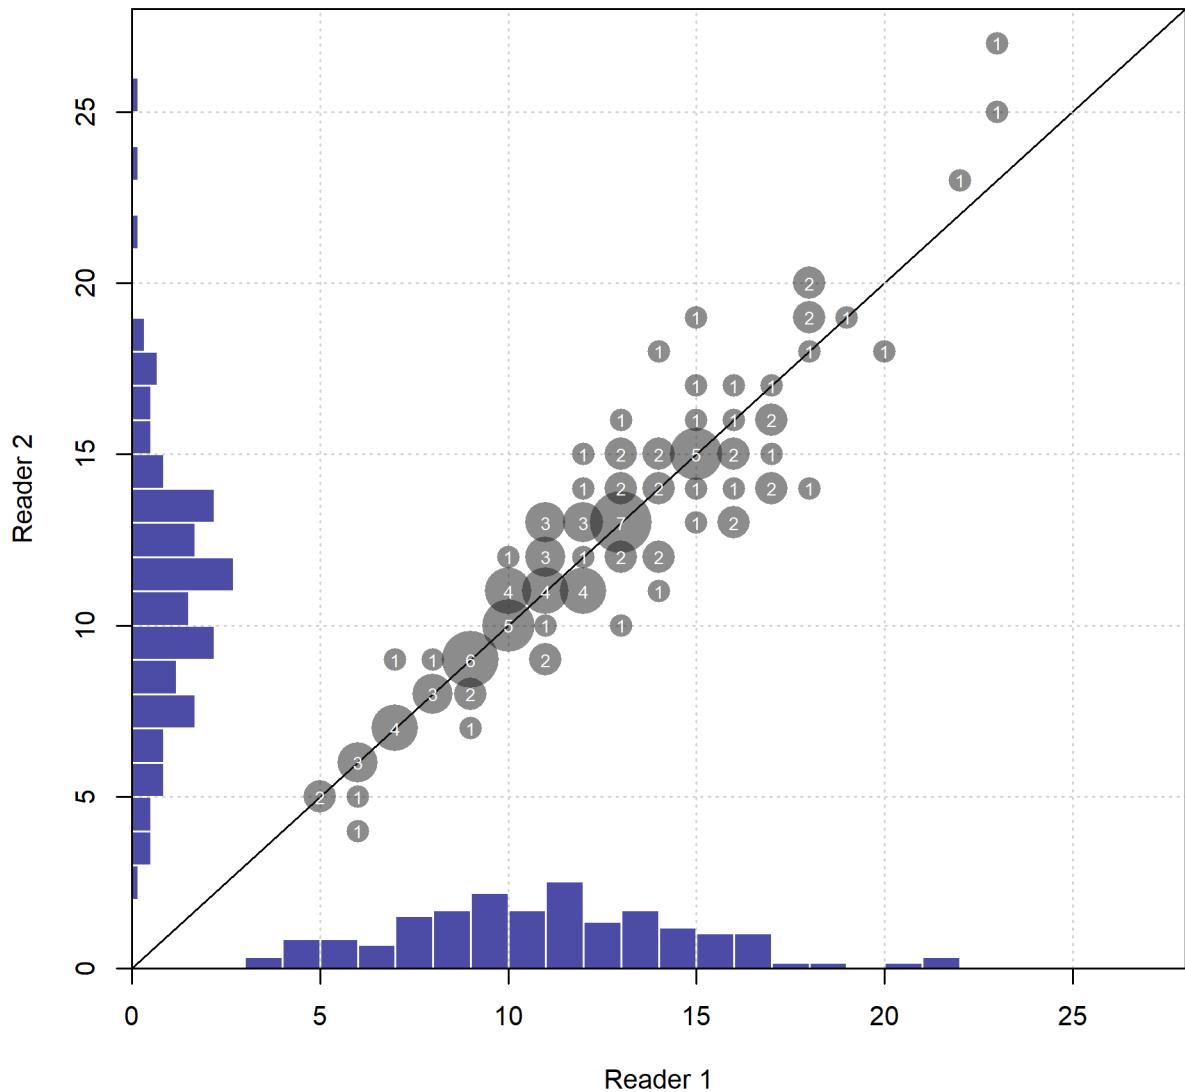

Figure 35: Aging precision between initial and blind double reads for GBYR. Numbers in the bubbles are the sample sizes of otoliths cross-read.

Reads(dot), Sd(blue), expected_read(red solid line),
and 95% CI for expected_read(red dotted line)

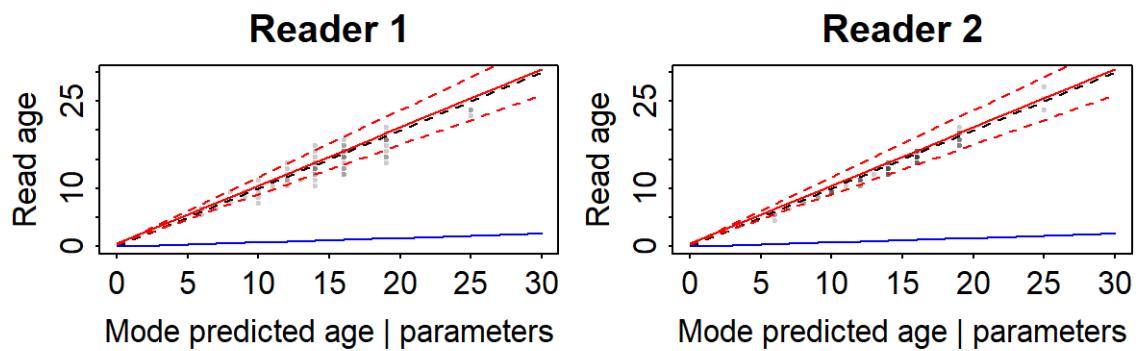

Figure 36: True versus predicted age for two current age readers at the NWFSC from the ageing error software with unbiased reads and curvilinear standard deviation for both readers.

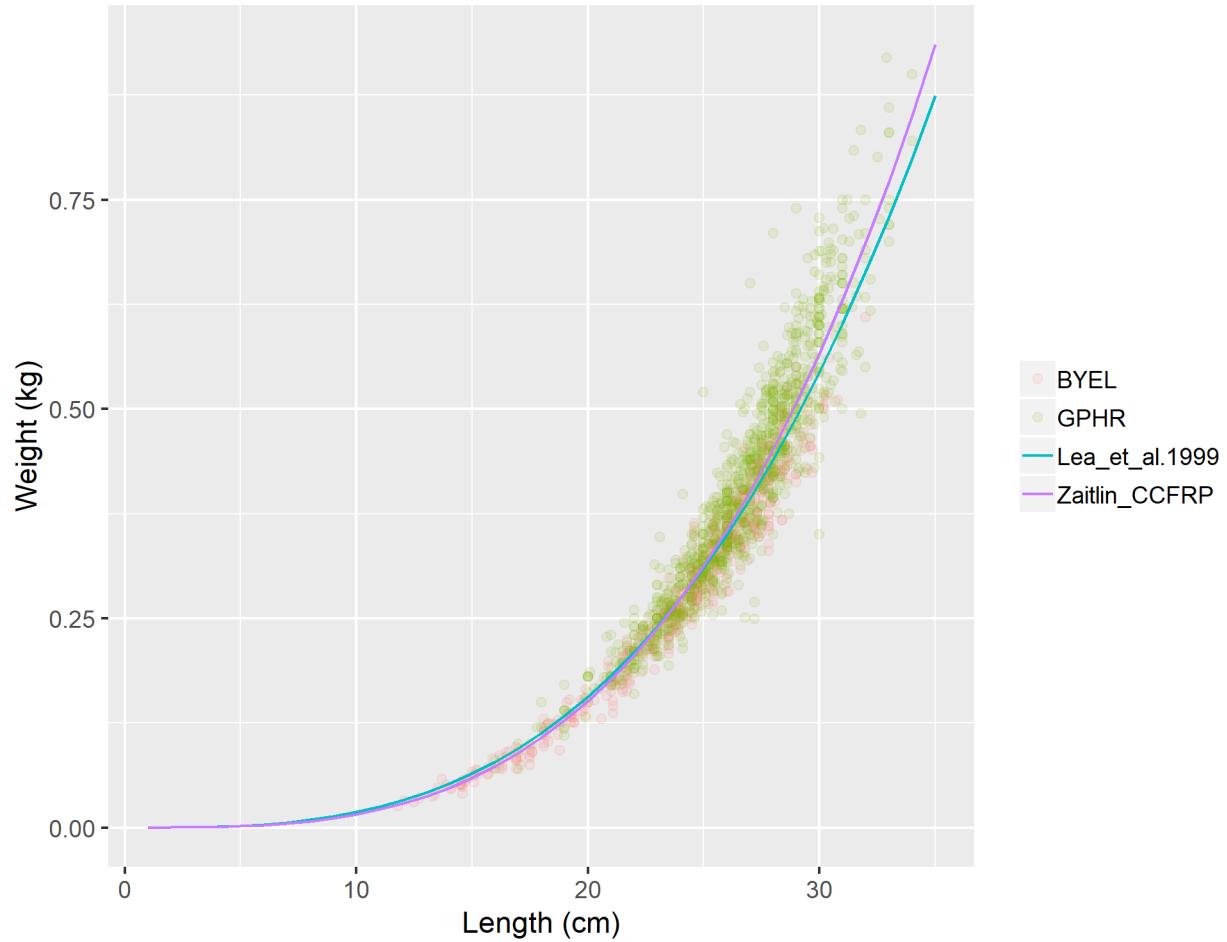

Figure 37: Comparison of the gopher rockfish weight-length curves from Lee et al. (1999) and tha estimated from black-and-yellow rockfishes from Zaitlin (1986), and gopher rockfishes from Loury (2011) and Meyers-Cherry(2014). The estimated curve from the current data is used in this assessment.

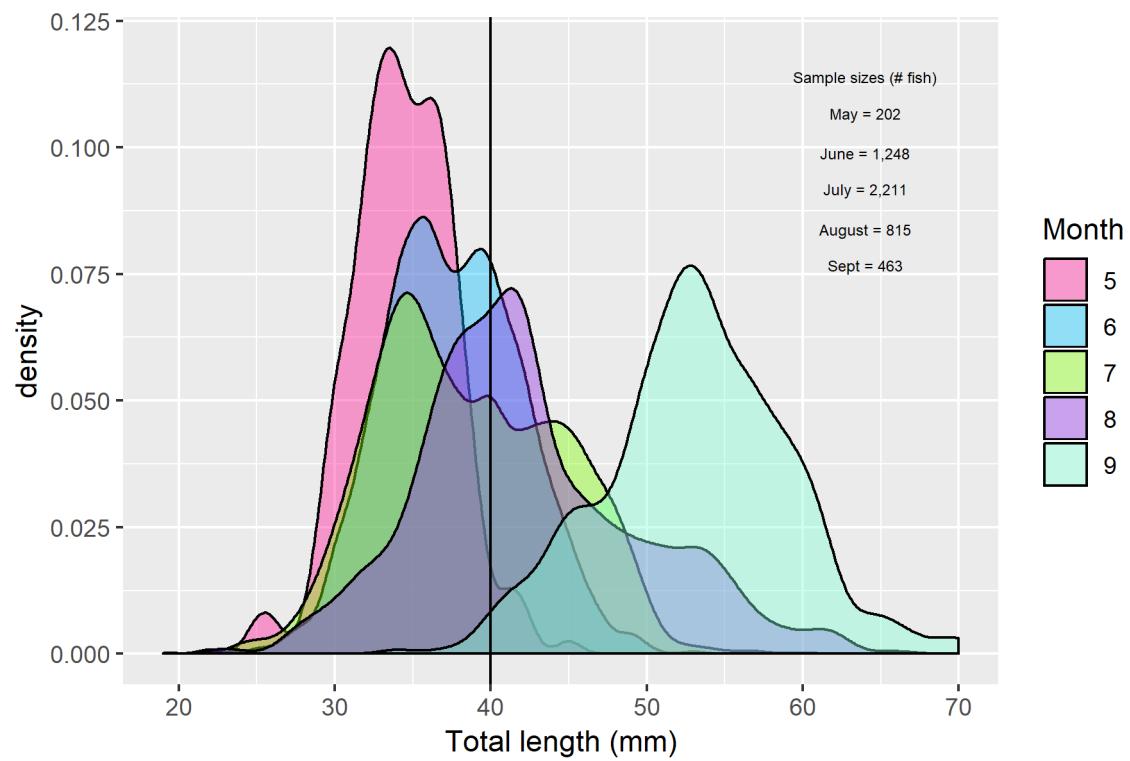

Figure 38: Length distribution by month for GBYR captured using a sampling tool called a Standard Monitoring Unit for the Recruitment of Fishes (SMURFs) from the UCSC-PISCO kelp forest fish survey, specifically as part of Diana Baetscher's dissertation work (Baetscher 2019).

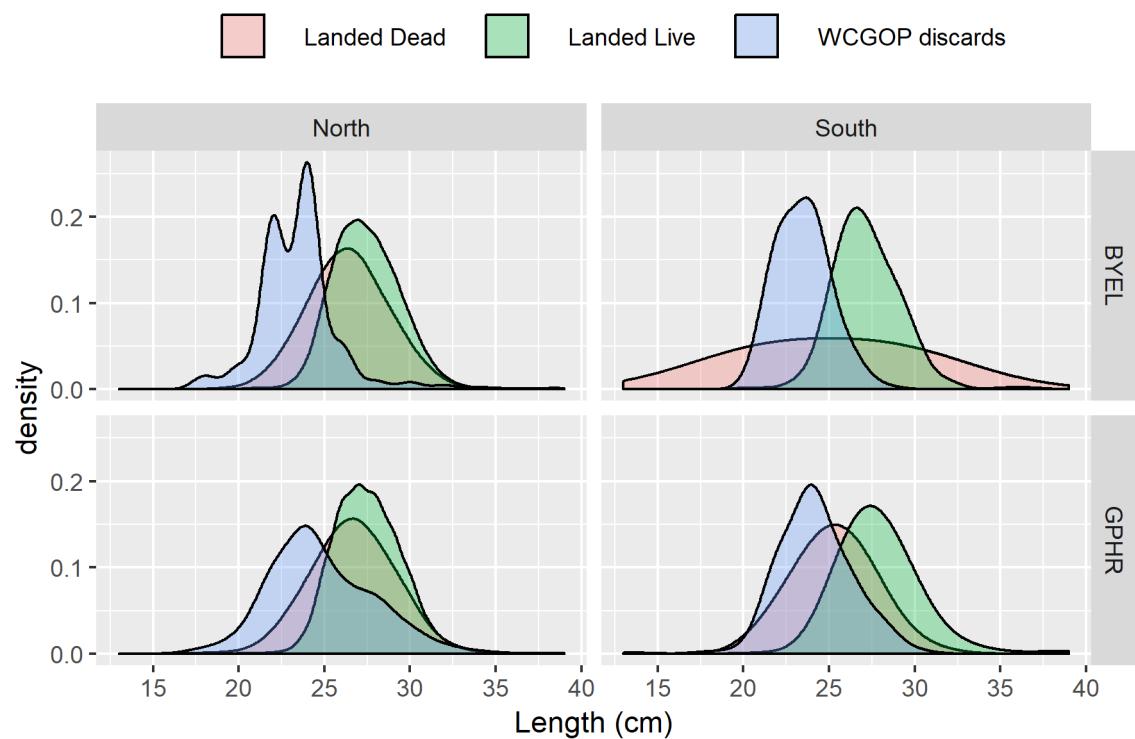

Figure 39: Length distributions of gopher and black-and-yellow rockfish for the commercial fleet and WCGOP discards north and south of Point Conception. The commercial landings were also separated between fish landed live and fish landed dead for this figure.

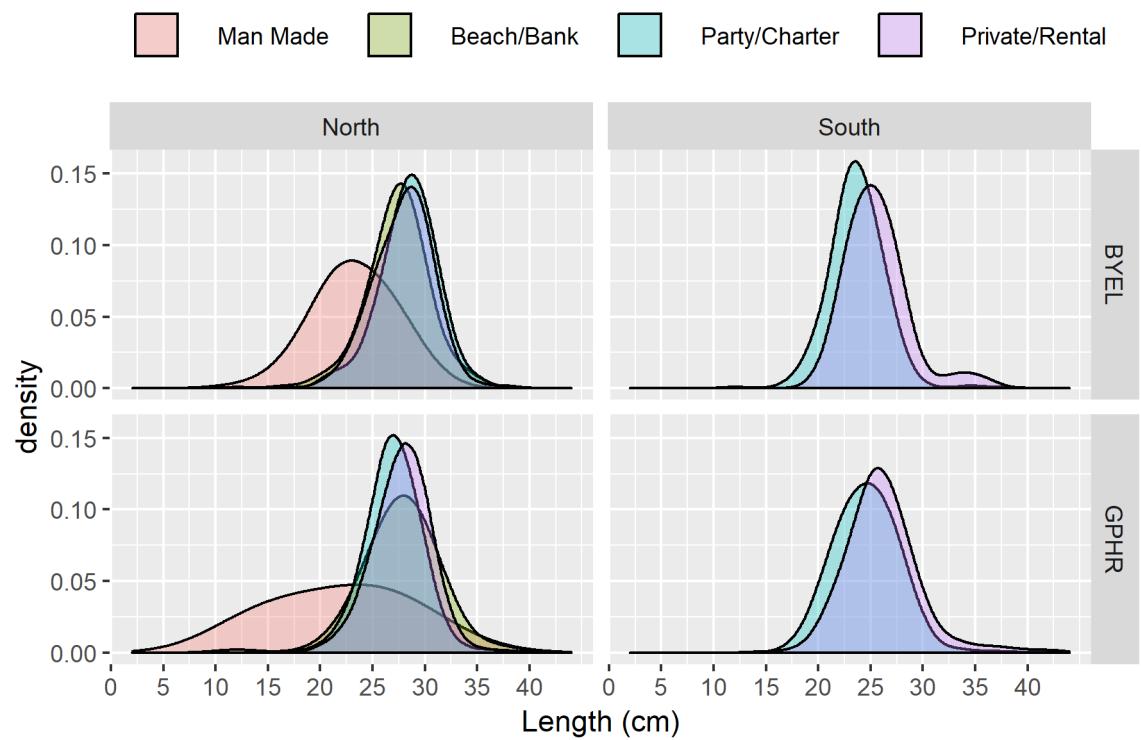

Figure 40: Length distributions of gopher and black-and-yellow rockfish for the recreational fleet north and south of Point Conception and by mode.

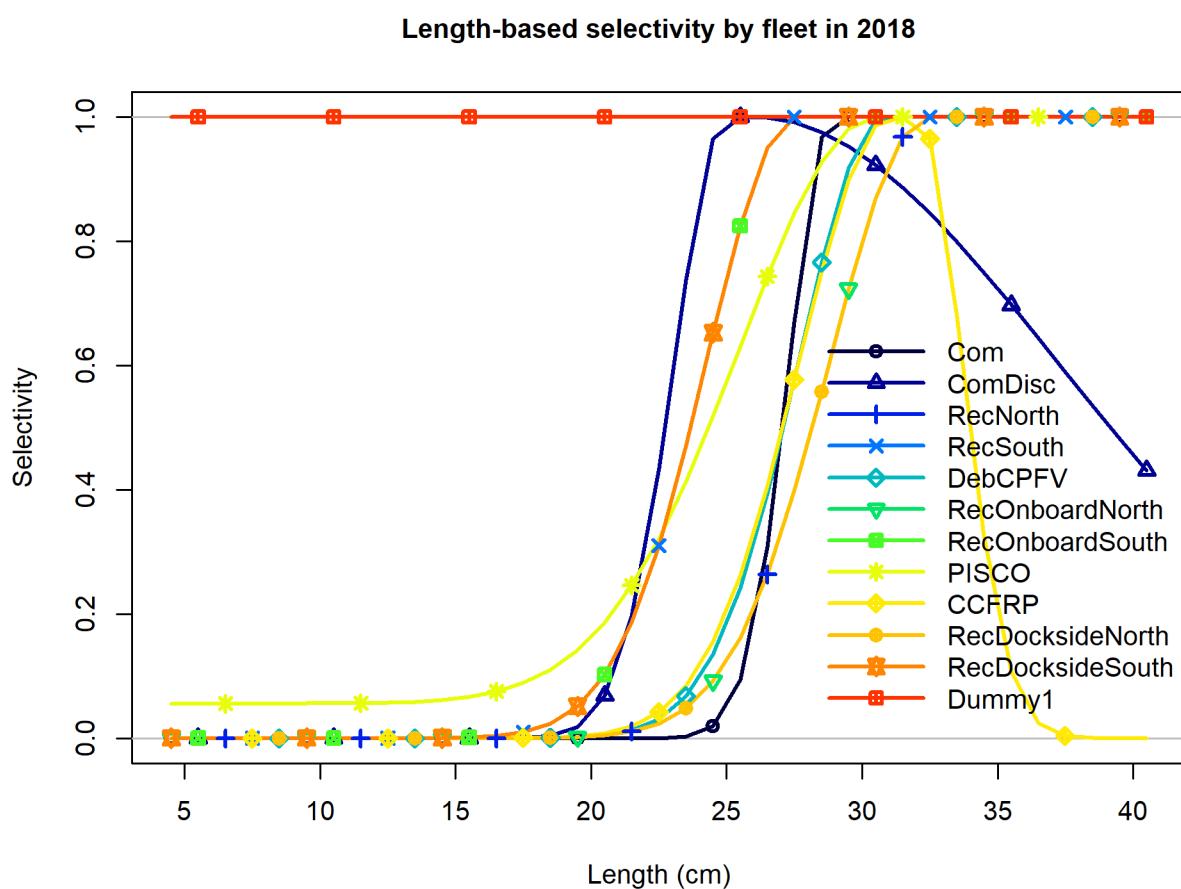

Figure 41: Selectivity at length for all of the fleets in the base model.

Time-varying selectivity for Com

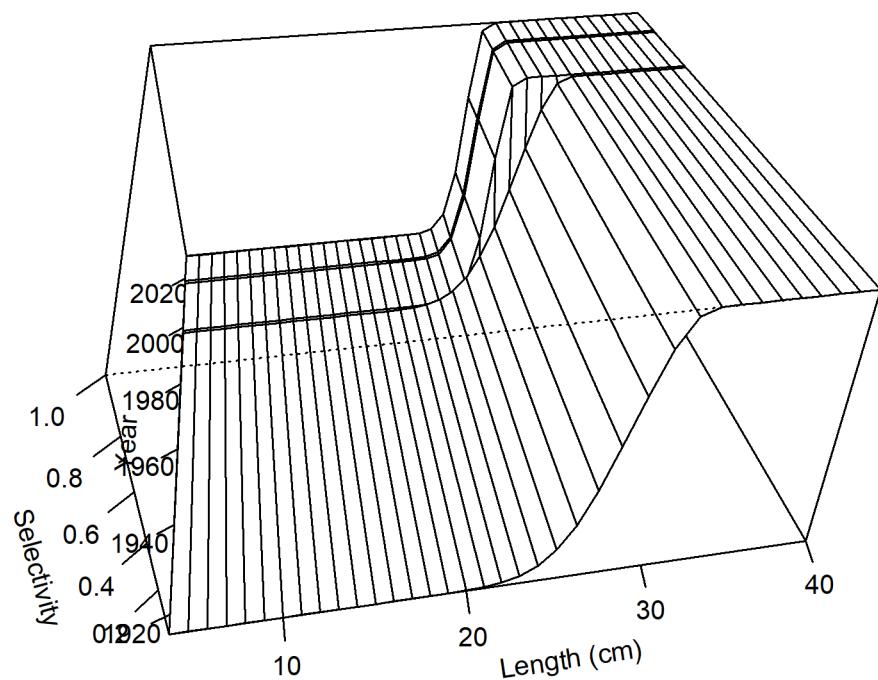

Figure 42: Surface plot of Female time-varying selectivity for the commercial fleet, with time blocks from 1916-1998 and 1999-2018.

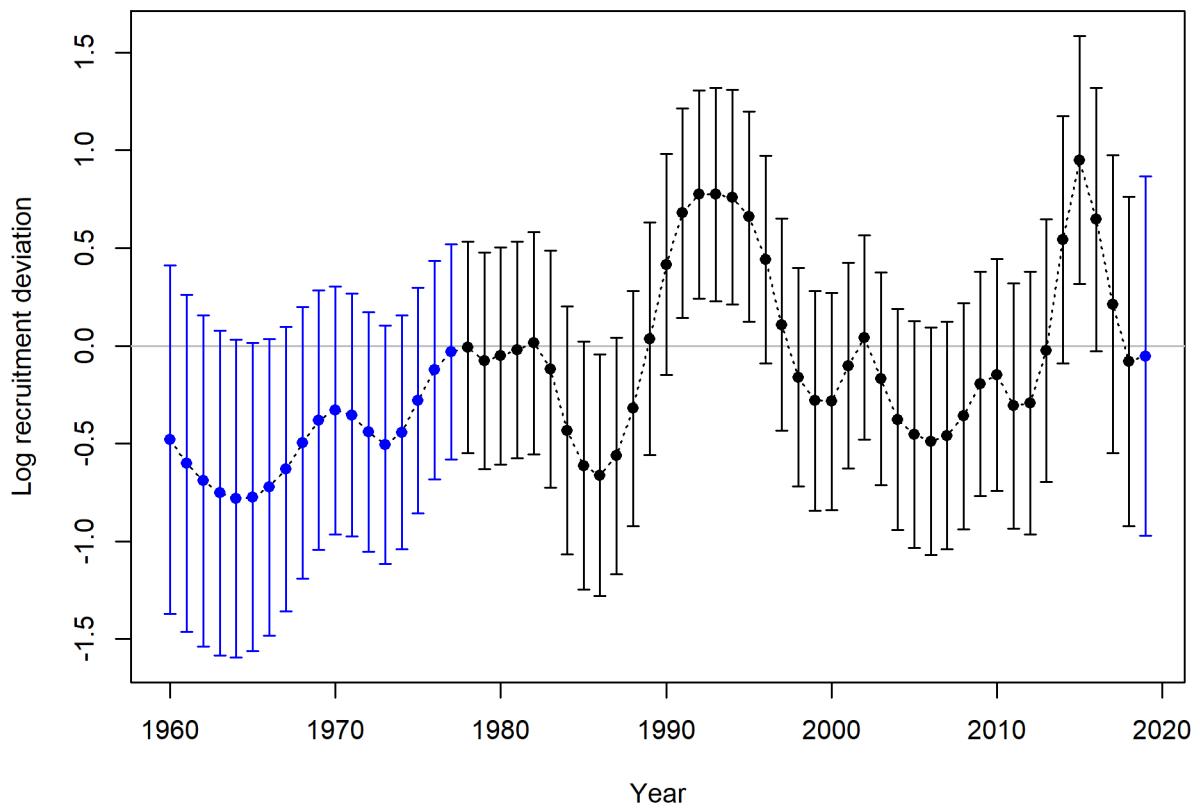

Figure 43: Estimated time-series of recruitment deviations for GBYR with 95% intervals.

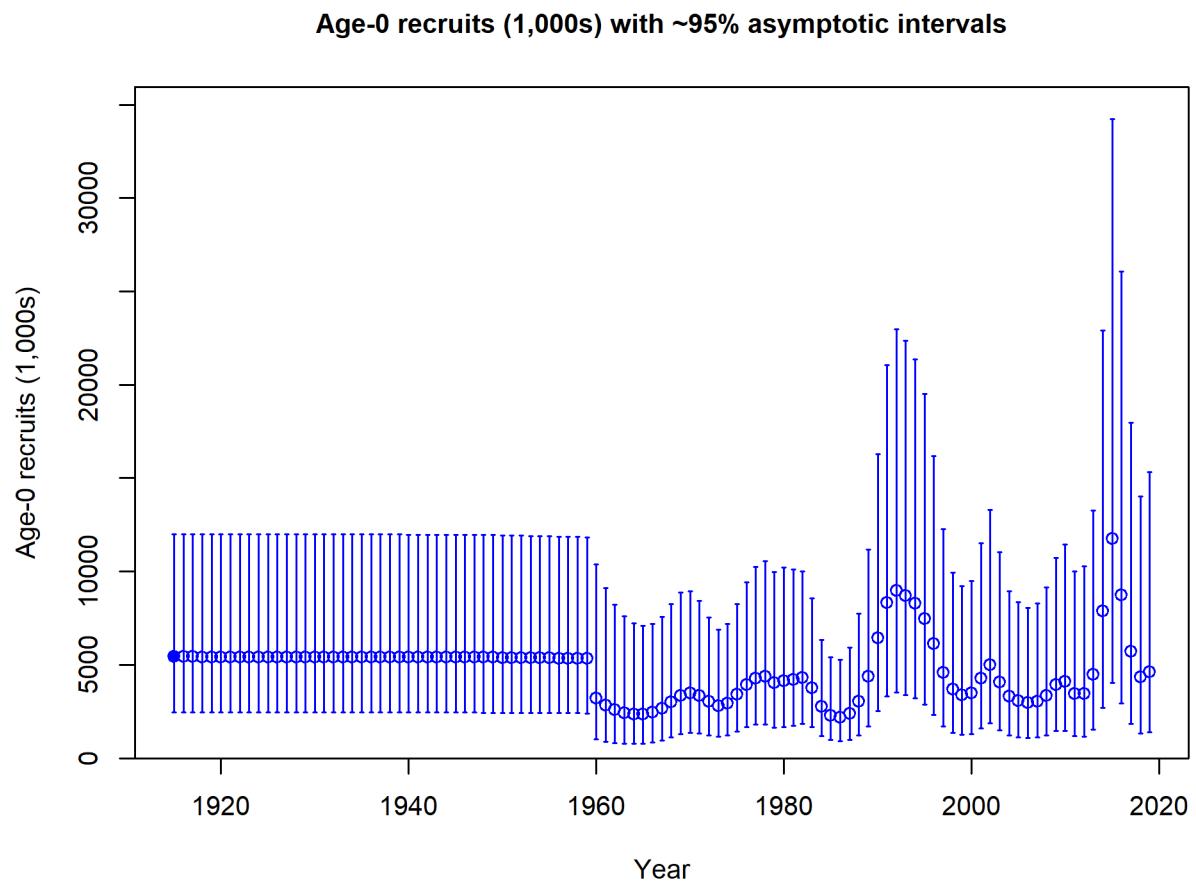

Figure 44: Time series of estimated GBYR recruitments for the base-case model with 95% confidence or credibility intervals.

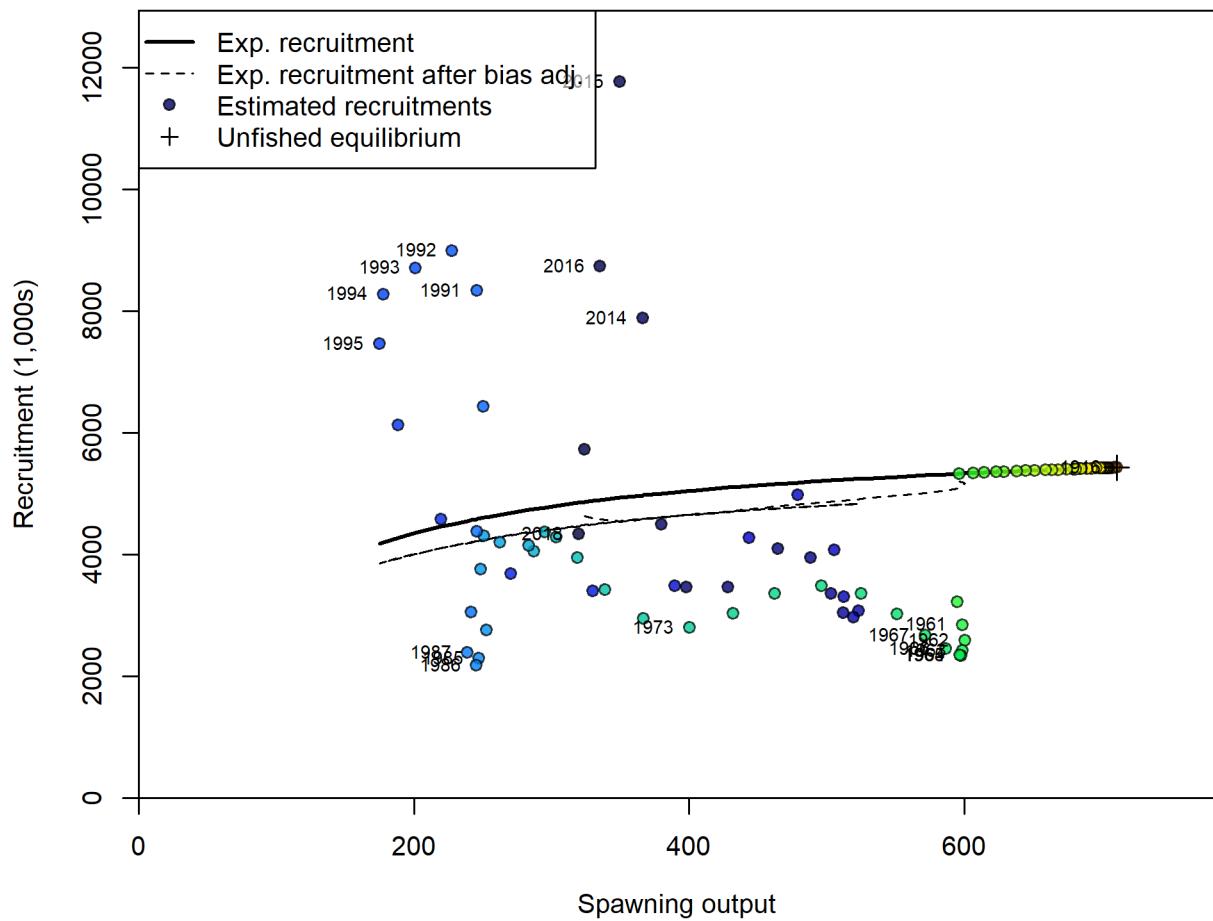

Figure 45: Estimated recruitment (red circles) and the assumed stock-recruit relationship (black line) for GBYR. The green line shows the effect of the bias correction for the lognormal distribution.

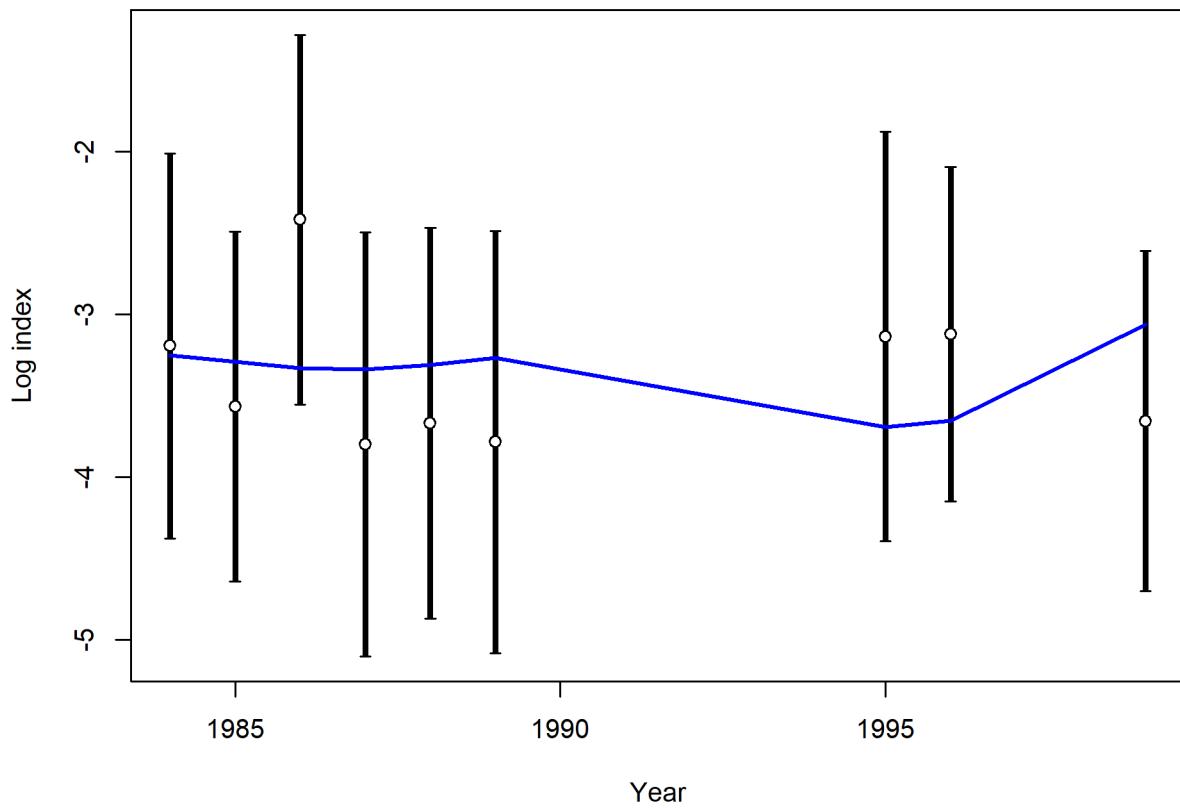

Figure 46: Fit to log index data on log scale for the recreational MRFSS dockside CPFV fishery north of Point Conception. Lines indicate 95% uncertainty interval around index values. Thicker lines indicate input uncertainty before addition of estimated additional uncertainty parameter.

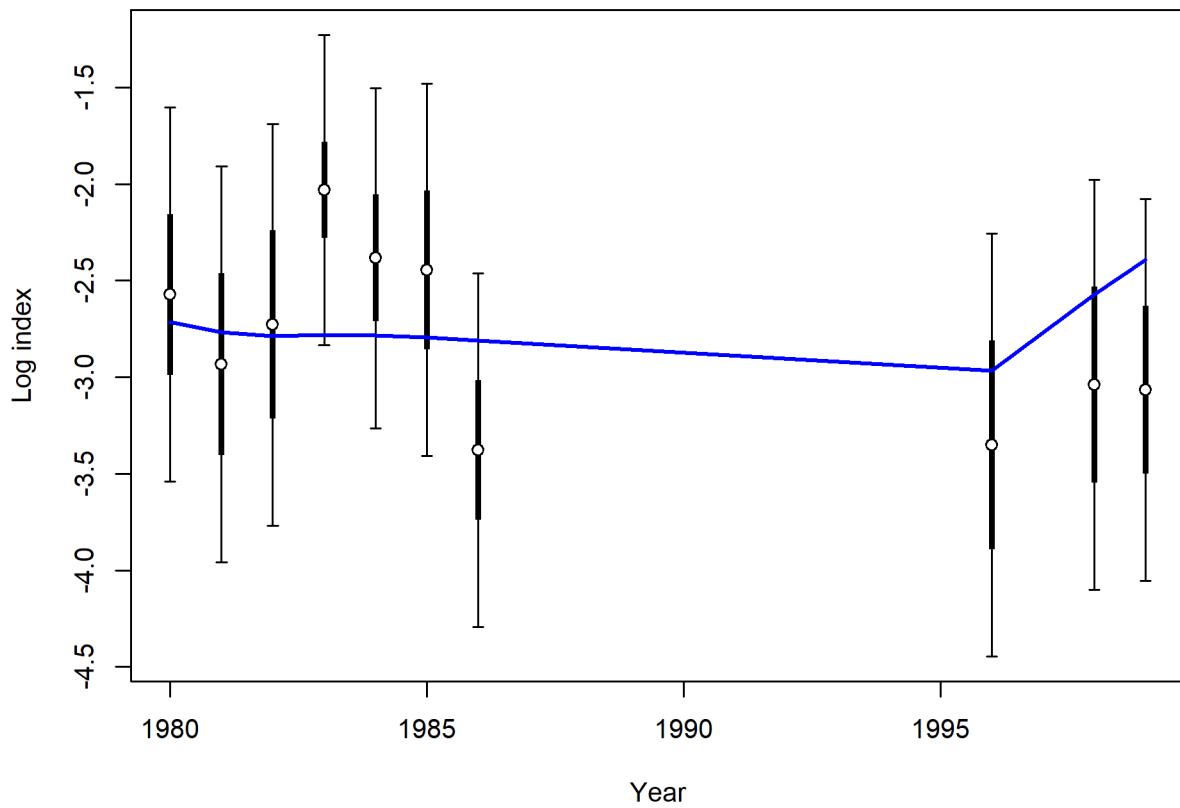

Figure 47: Fit to log index data on log scale for the recreational MRFSS dockside CPFV fishery south of Point Conception. Lines indicate 95% uncertainty interval around index values. Thicker lines indicate input uncertainty before addition of estimated additional uncertainty parameter.

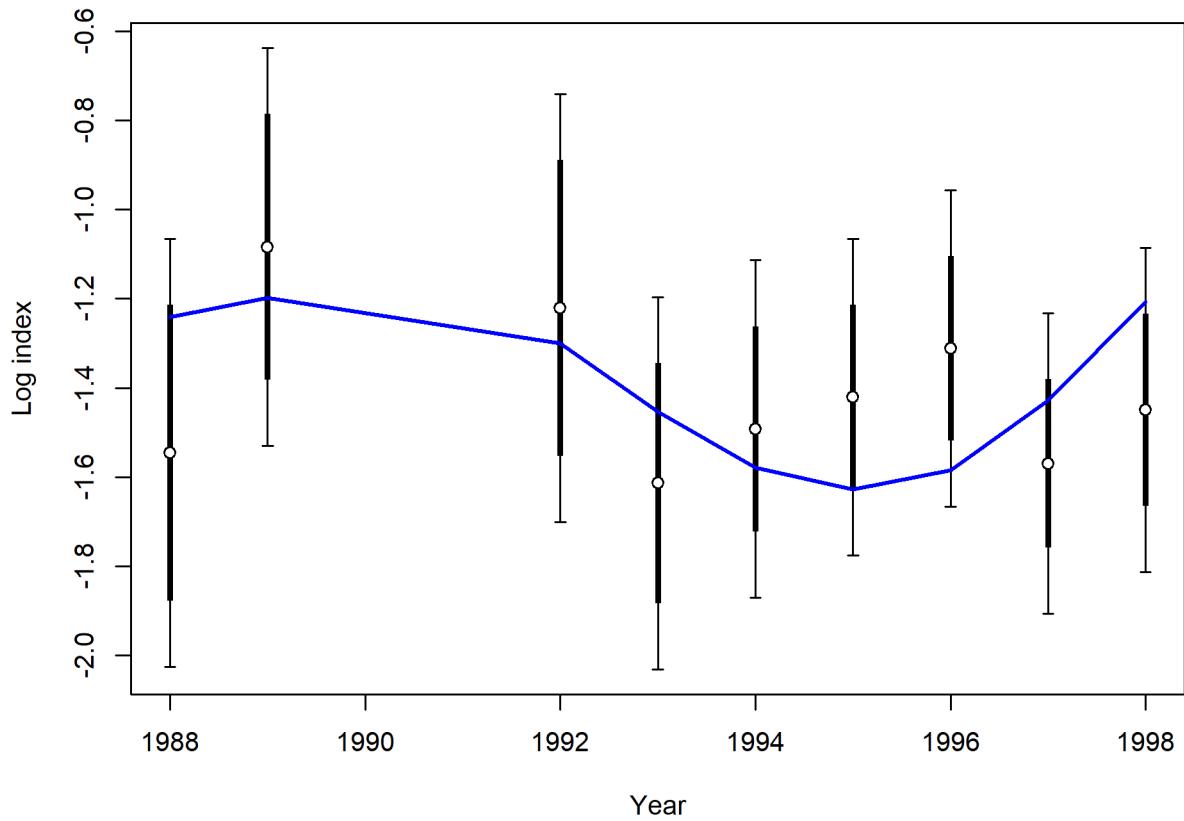

Figure 48: Fit to log index data on log scale for the recerational Deb's CPFV onboard observer program, representing north of Point Conception. Lines indicate 95% uncertainty interval around index values. Thicker lines indicate input uncertainty before addition of estimated additional uncertainty parameter.

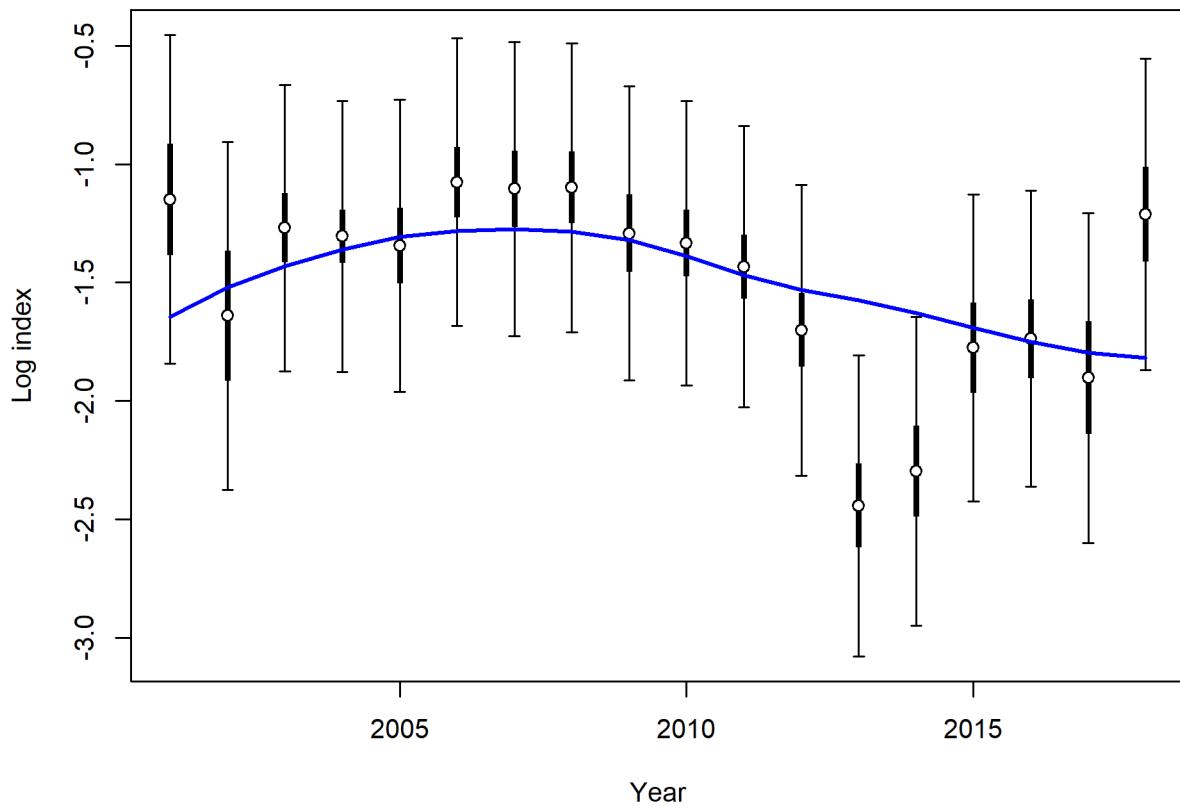

Figure 49: Fit to log index data on log scale for the recerational current CPFV onboard observer program north of Point Conception. Lines indicate 95% uncertainty interval around index values. Thicker lines indicate input uncertainty before addition of estimated additional uncertainty parameter.

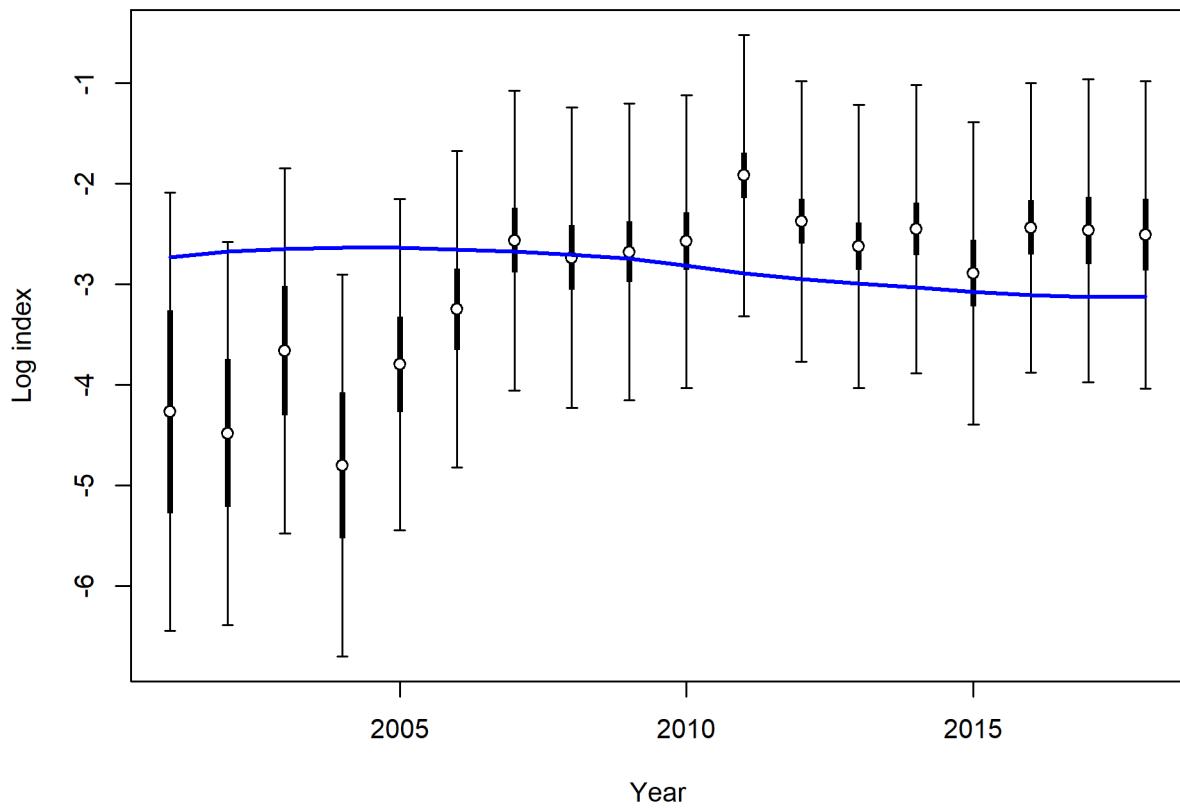

Figure 50: Fit to log index data on log scale for the recerational current CPFV onboard observer program south of Point Conception. Lines indicate 95% uncertainty interval around index values. Thicker lines indicate input uncertainty before addition of estimated additional uncertainty parameter.

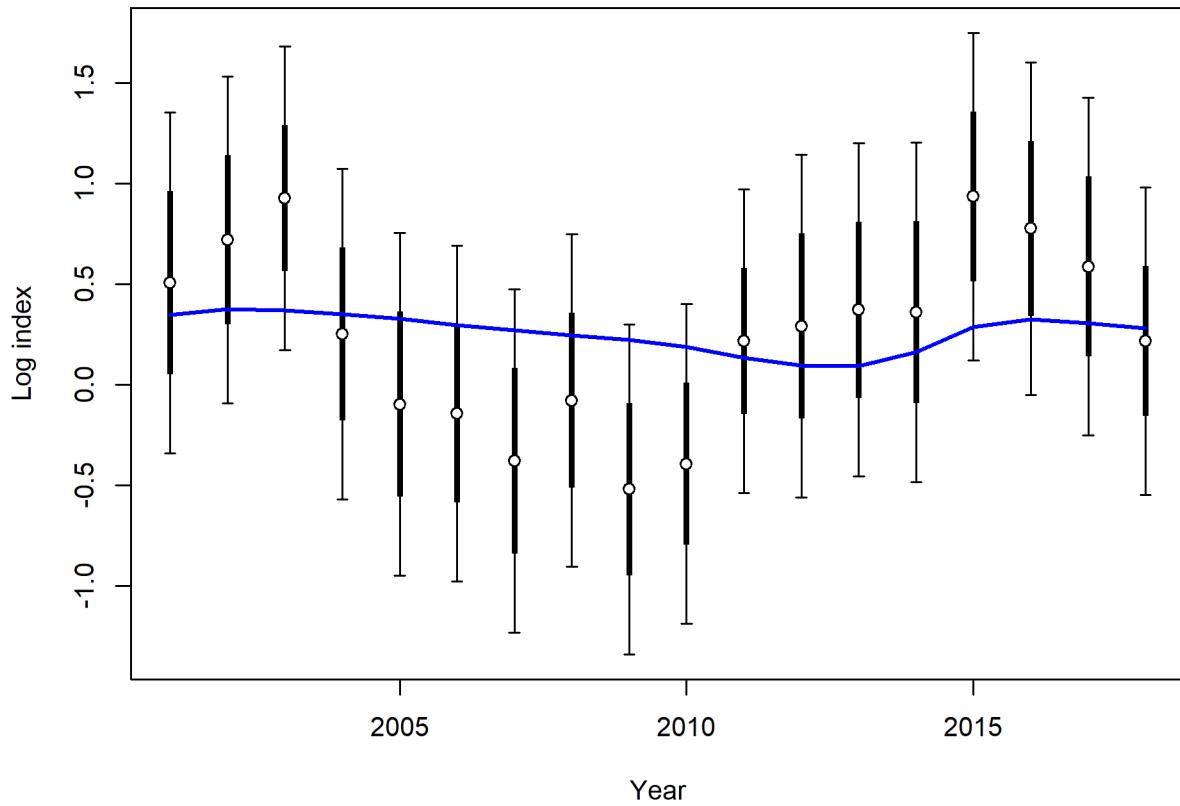

Figure 51: Fit to log index data on log scale for the fishery-independent PISCO kelp forest fish survey. Lines indicate 95% uncertainty interval around index values. Thicker lines indicate input uncertainty before addition of estimated additional uncertainty parameter.

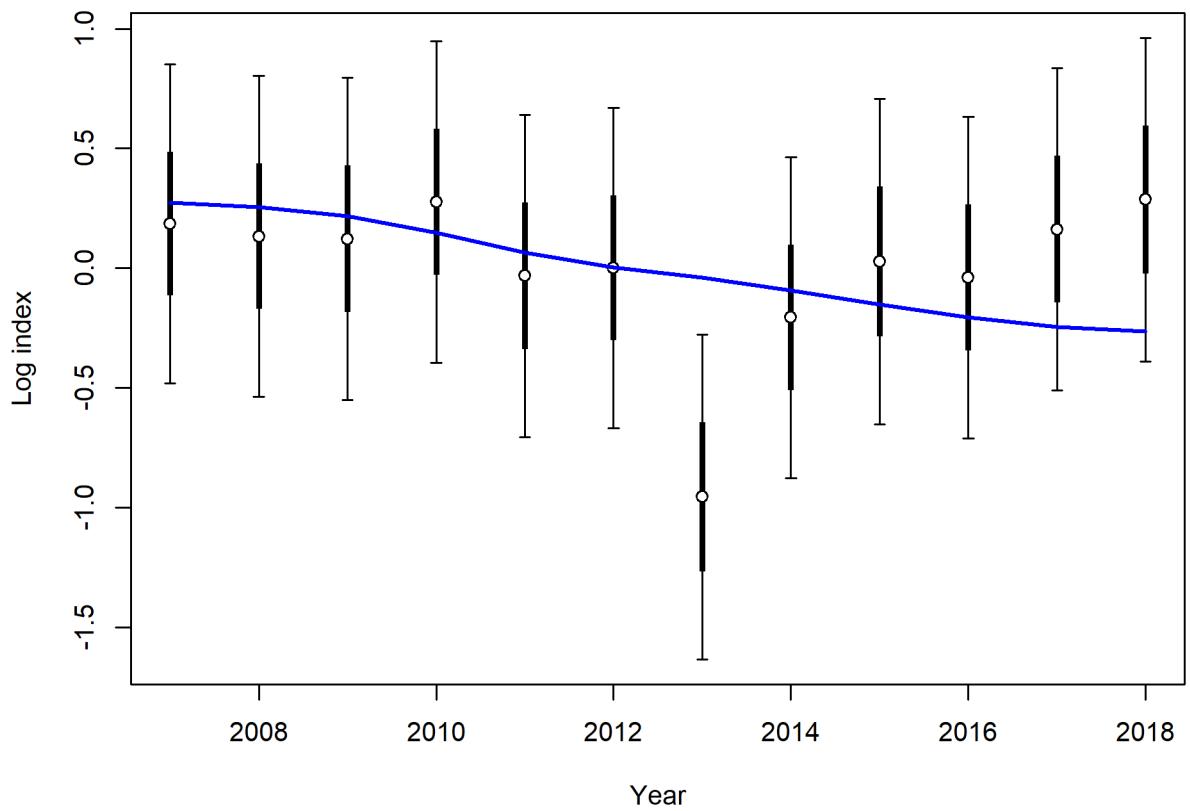

Figure 52: Fit to log index data on log scale for the fishery-independent CCFRP hook-and-line survey. Lines indicate 95% uncertainty interval around index values. Thicker lines indicate input uncertainty before addition of estimated additional uncertainty parameter.

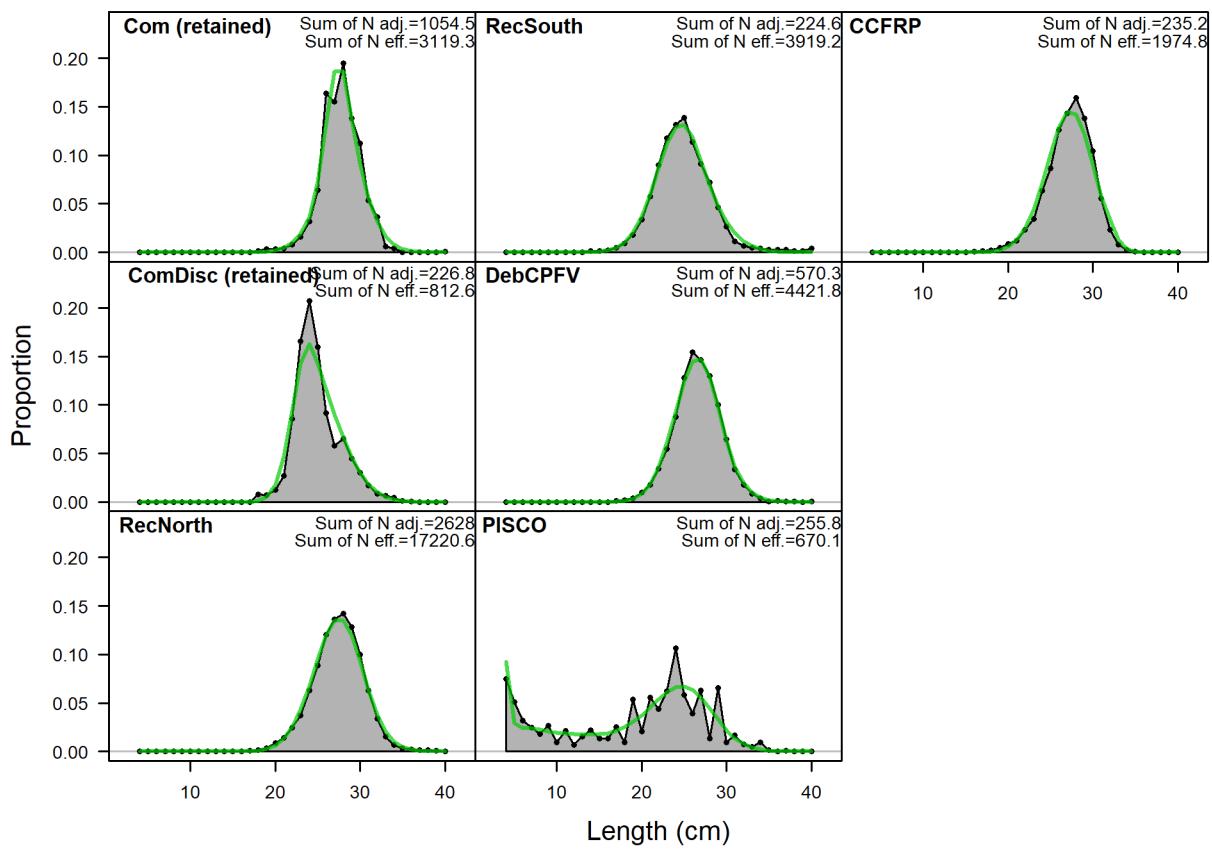

Figure 53: Length compositions aggregated across time by fleet.

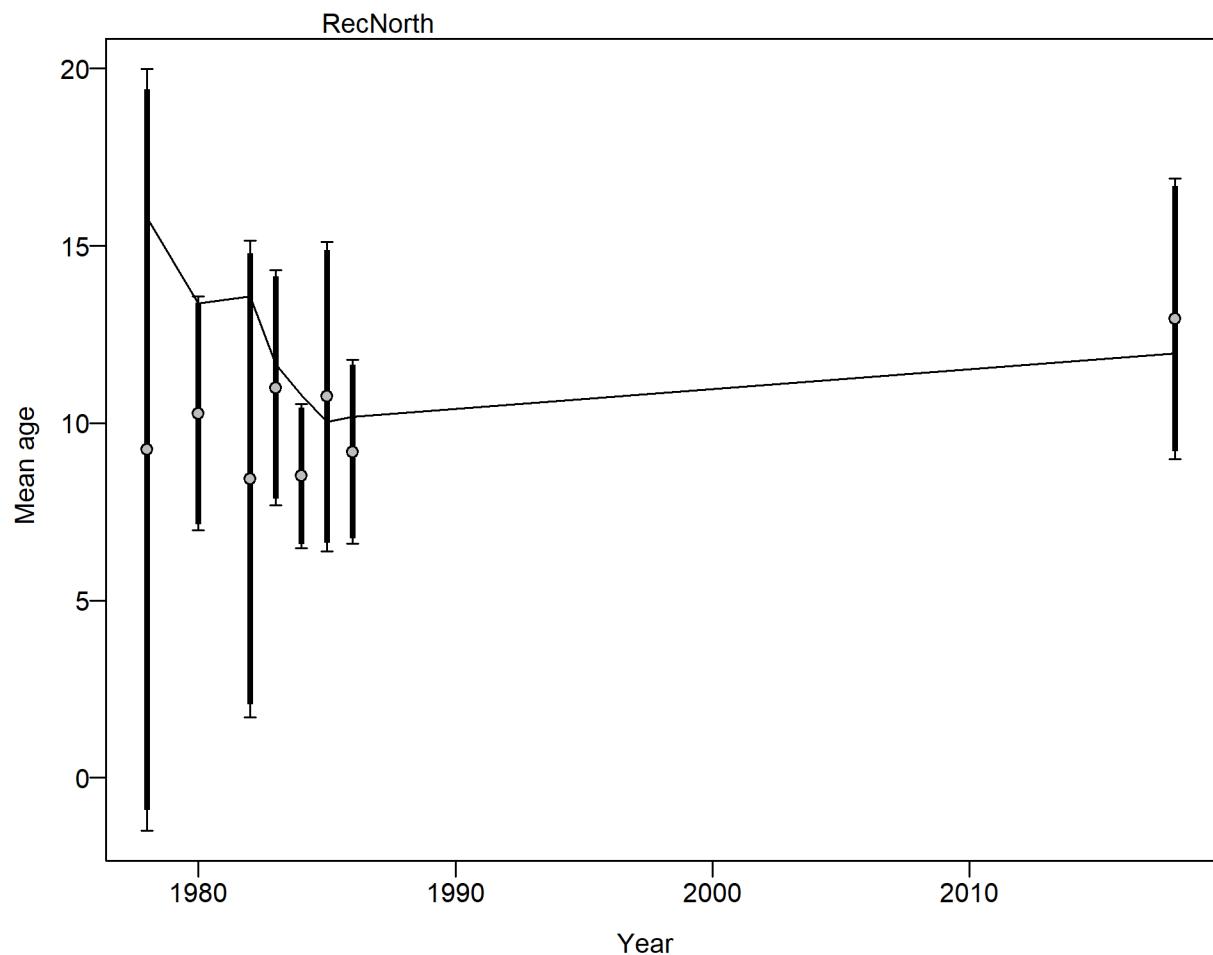

Figure 54: Mean age for the recreational fishery (ages from north of Point Conception only) with 95% confidence intervals based on current samples sizes. Francis data weighting method TA1.8: thinner intervals (with capped ends) show result of further adjusting sample sizes based on suggested multiplier (with 95% interval) is 0.028139 (0.378941-2.777483). For more info, see Francis et al. (2011).

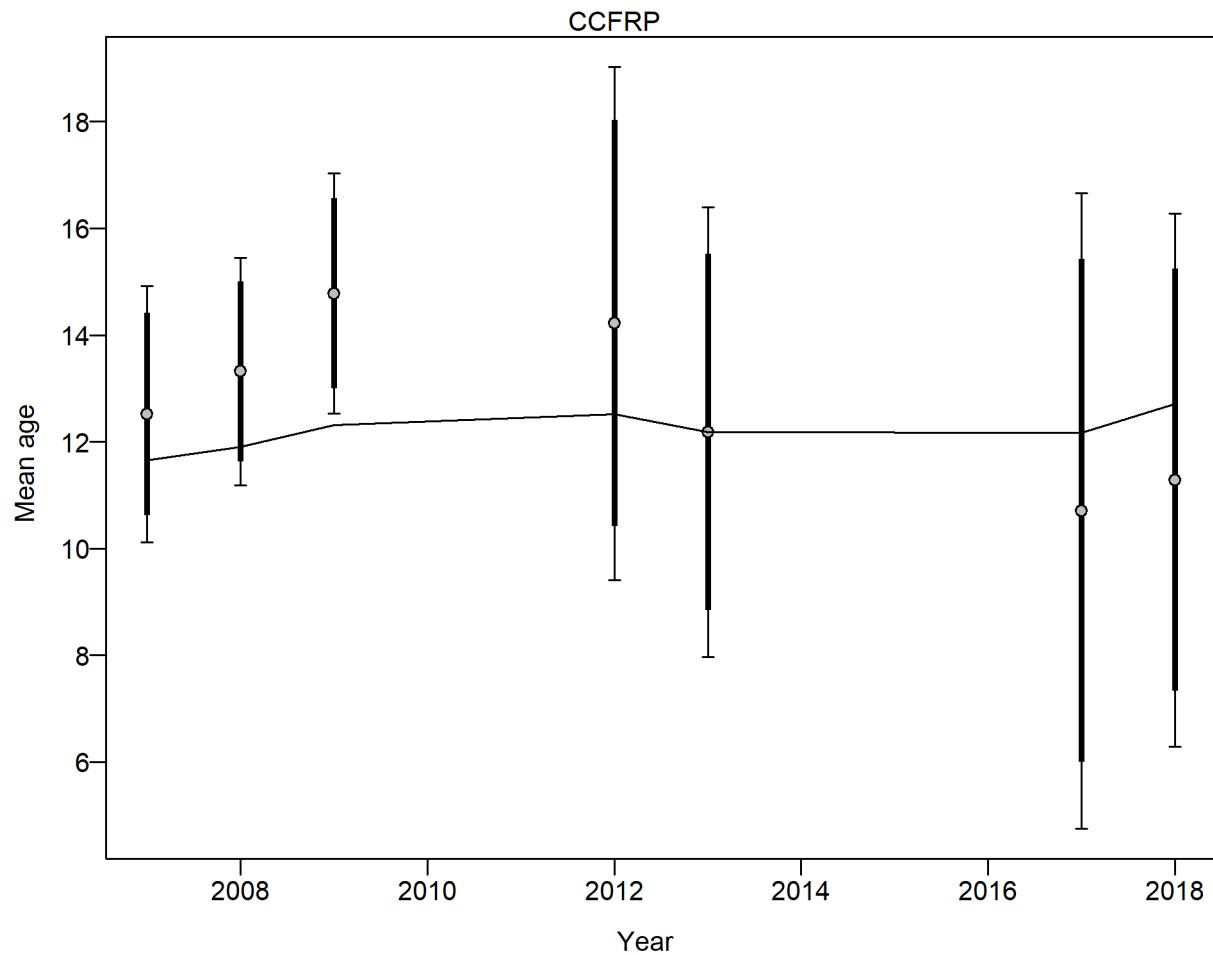

Figure 55: Mean age for the CCFRP survey with 95% confidence intervals based on current samples sizes. Francis data weighting method TA1.8: thinner intervals (with capped ends) show result of further adjusting sample sizes based on suggested multiplier (with 95% interval) is 0.072401 (0.359932-3.573706). For more info, see Francis et al. (2011).

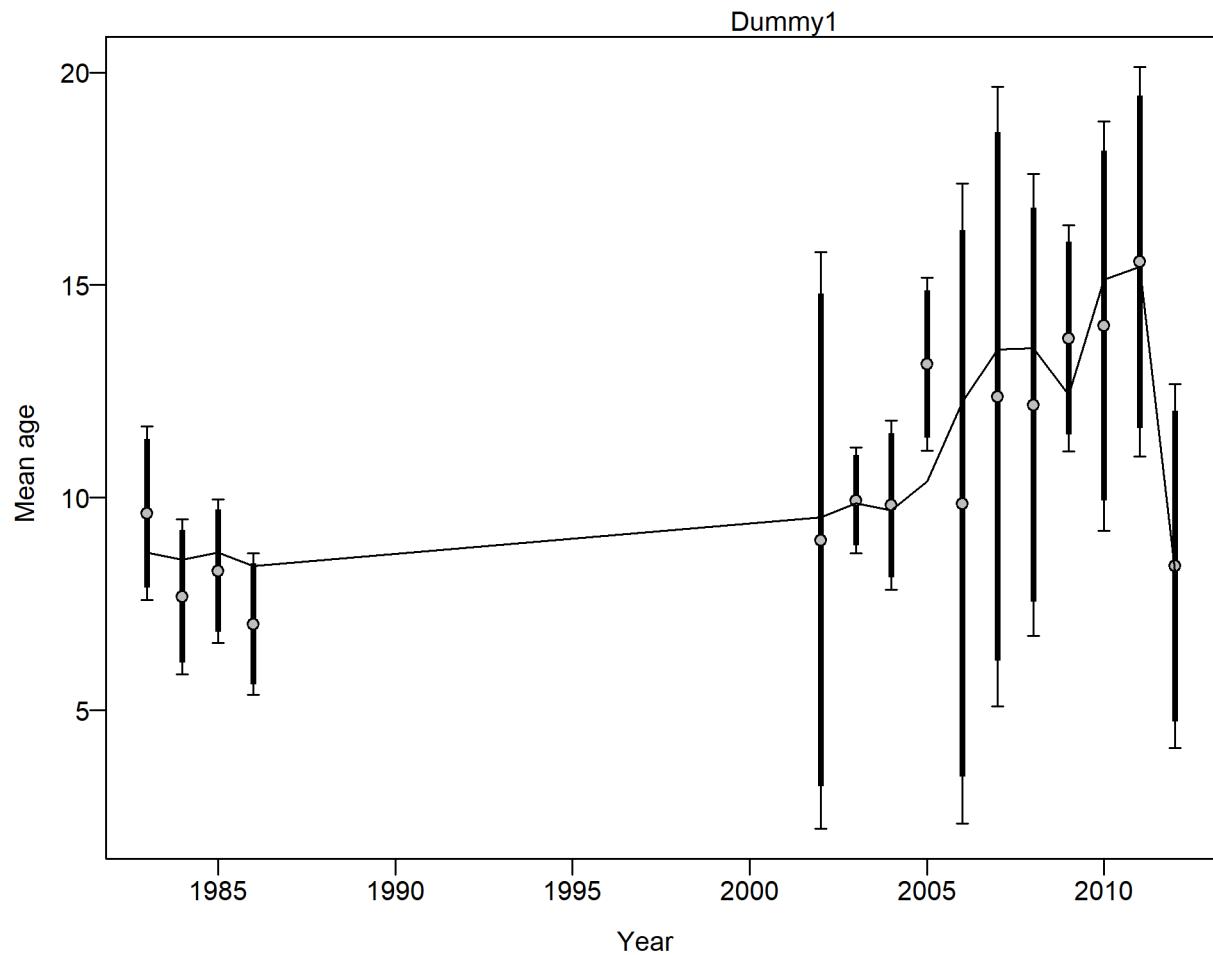

Figure 56: Mean age for the 'dummy' fleet with 95% confidence intervals based on current samples sizes. Francis data weighting method TA1.8: thinner intervals (with capped ends) show result of further adjusting sample sizes based on suggested multiplier (with 95% interval) is NA (NA-NA). For more info, see Francis et al. (2011).

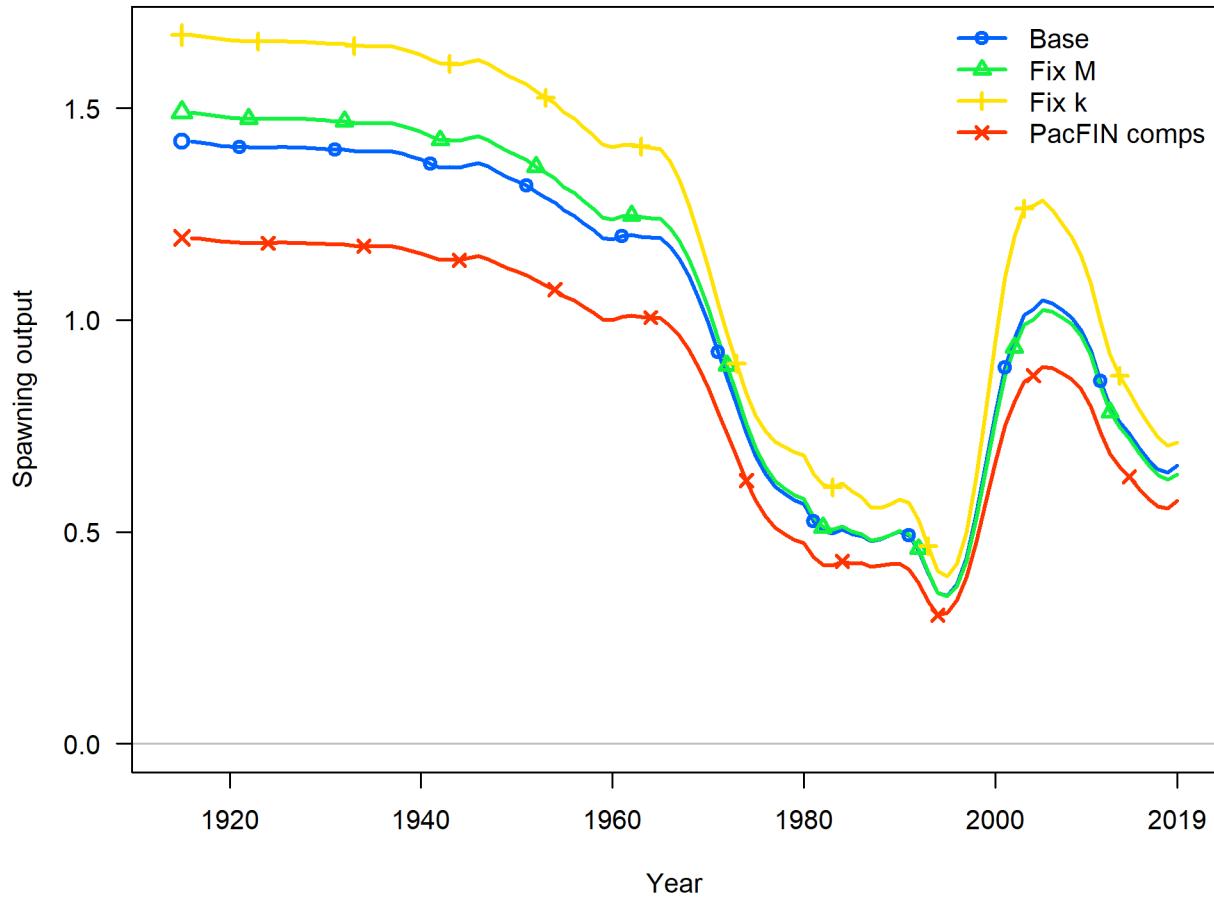

Figure 57: Sensitivity of the spawning biomass to fixing natural mortality to the prior, fixing the von Bertalanffy k parameter to the external estimate, or using commercial PacFIN length composition data instead of CALCOM, as compared to the pre-STAR base model.

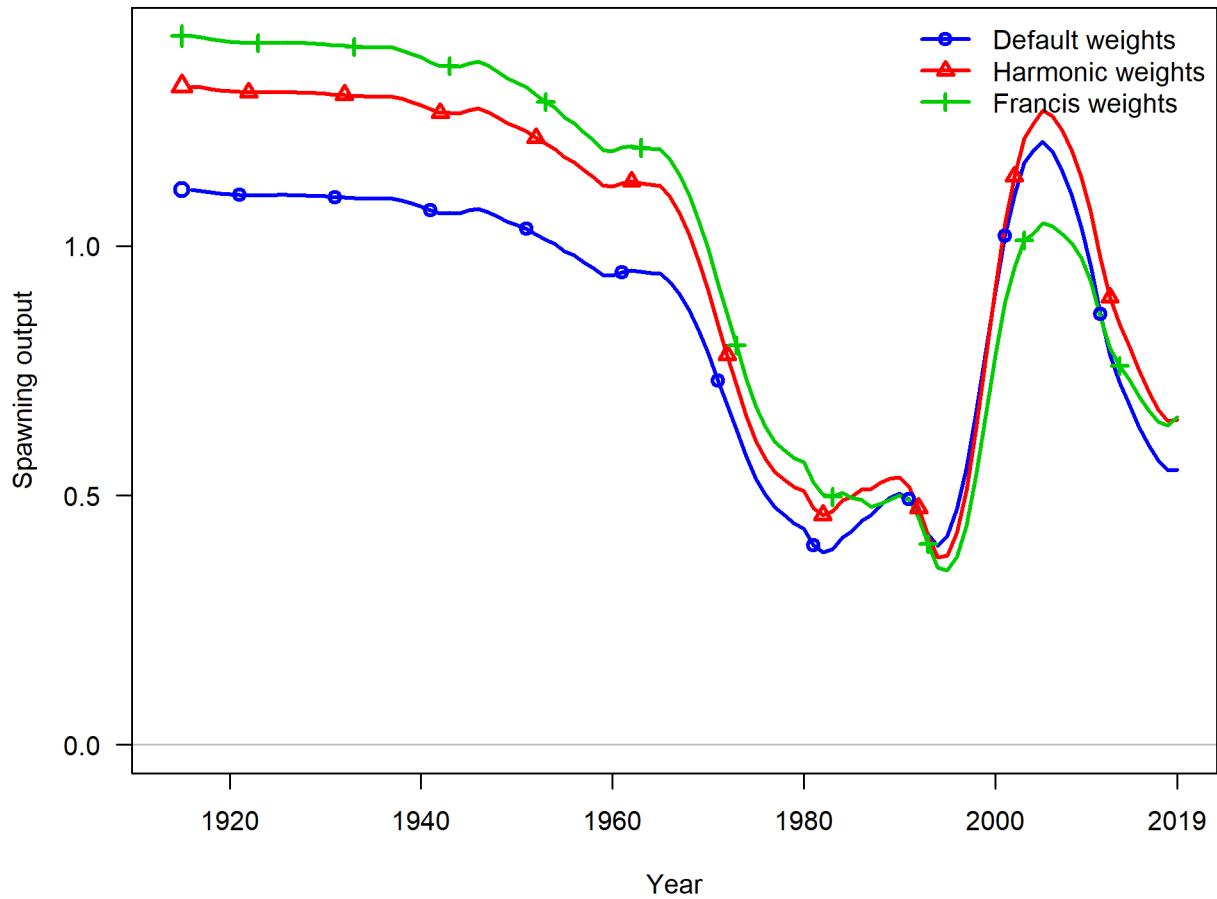

Figure 58: Sensitivity of the spawning biomass to either the default weight of composition data, the harmonic mean, or Francis weights.

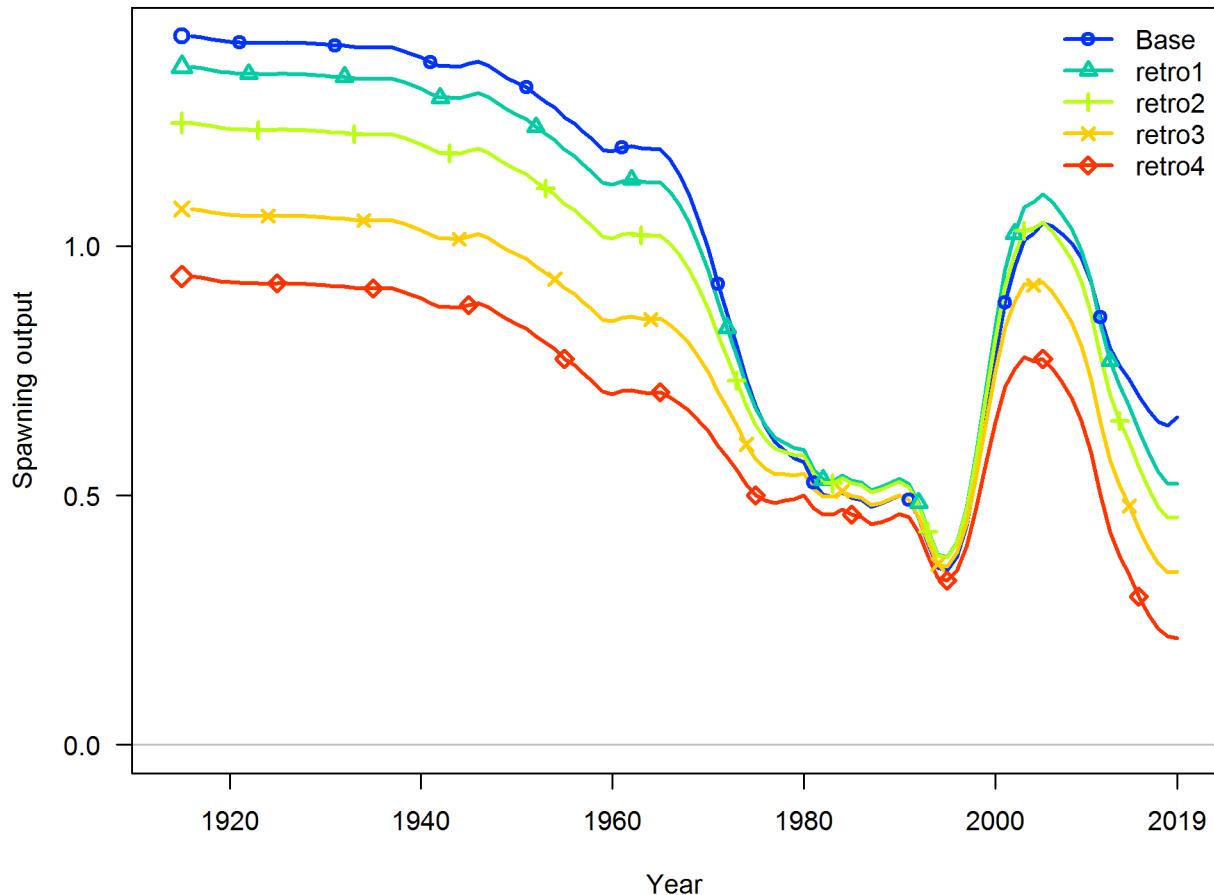

Figure 59: Retrospective pattern for spawning output.

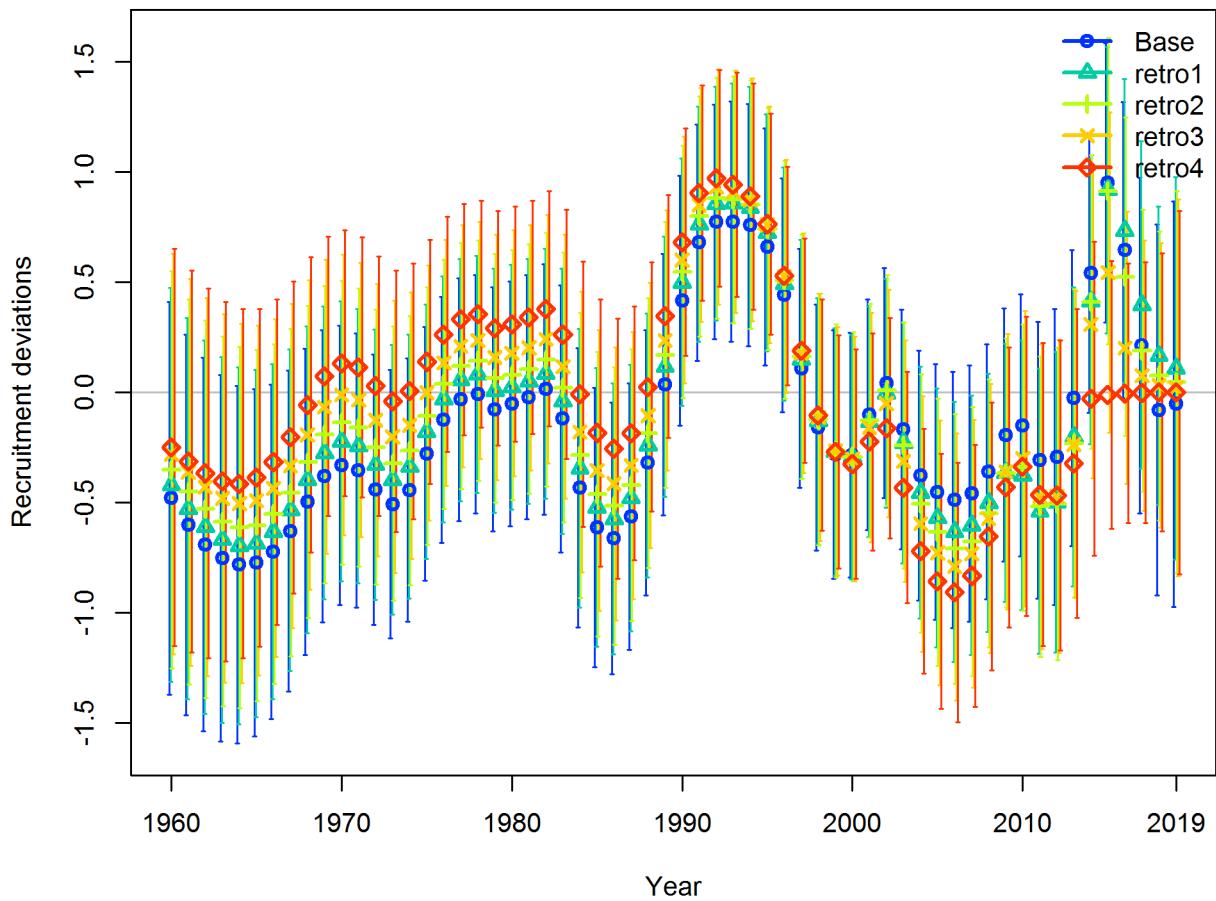

Figure 60: Retrospective pattern for estimated recruitment deviations.

Changes in length-composition likelihoods by fleet

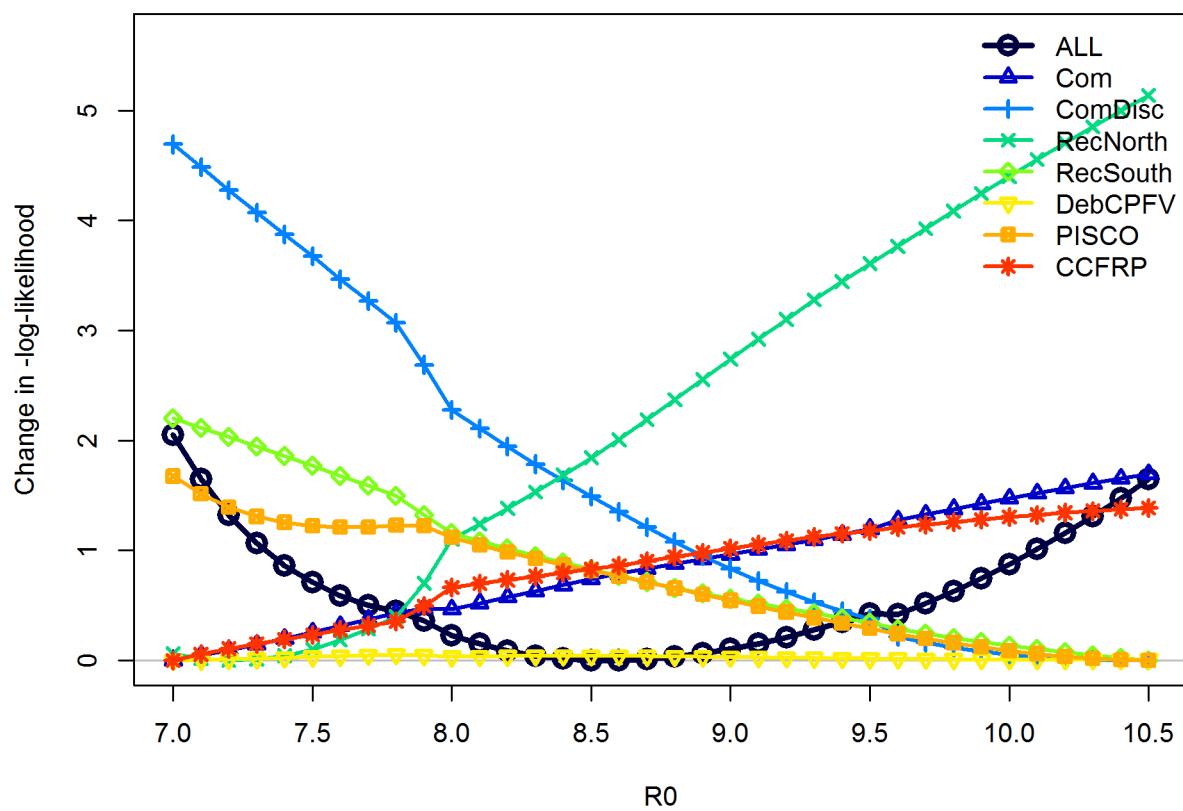

Figure 61: Likelihood profile across R_0 values by fleet.

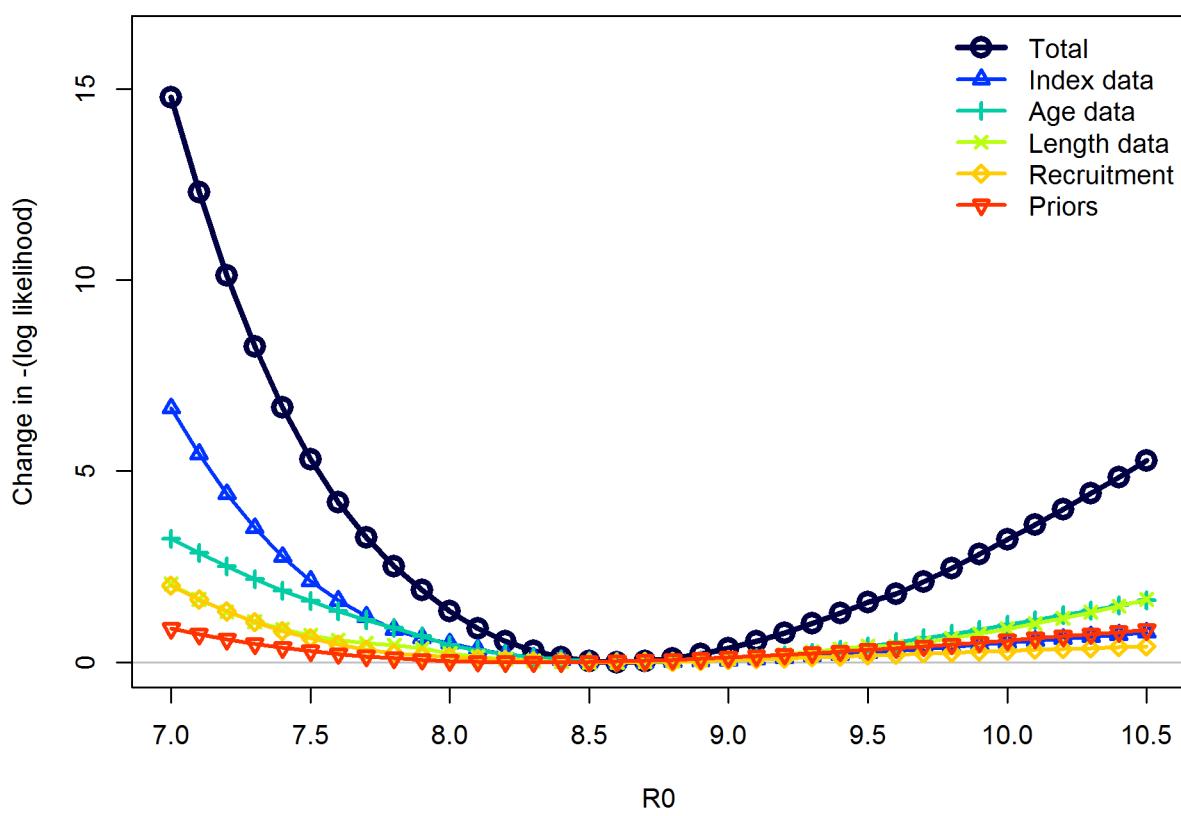

Figure 62: Likelihood profile across R_0 values for each data type.

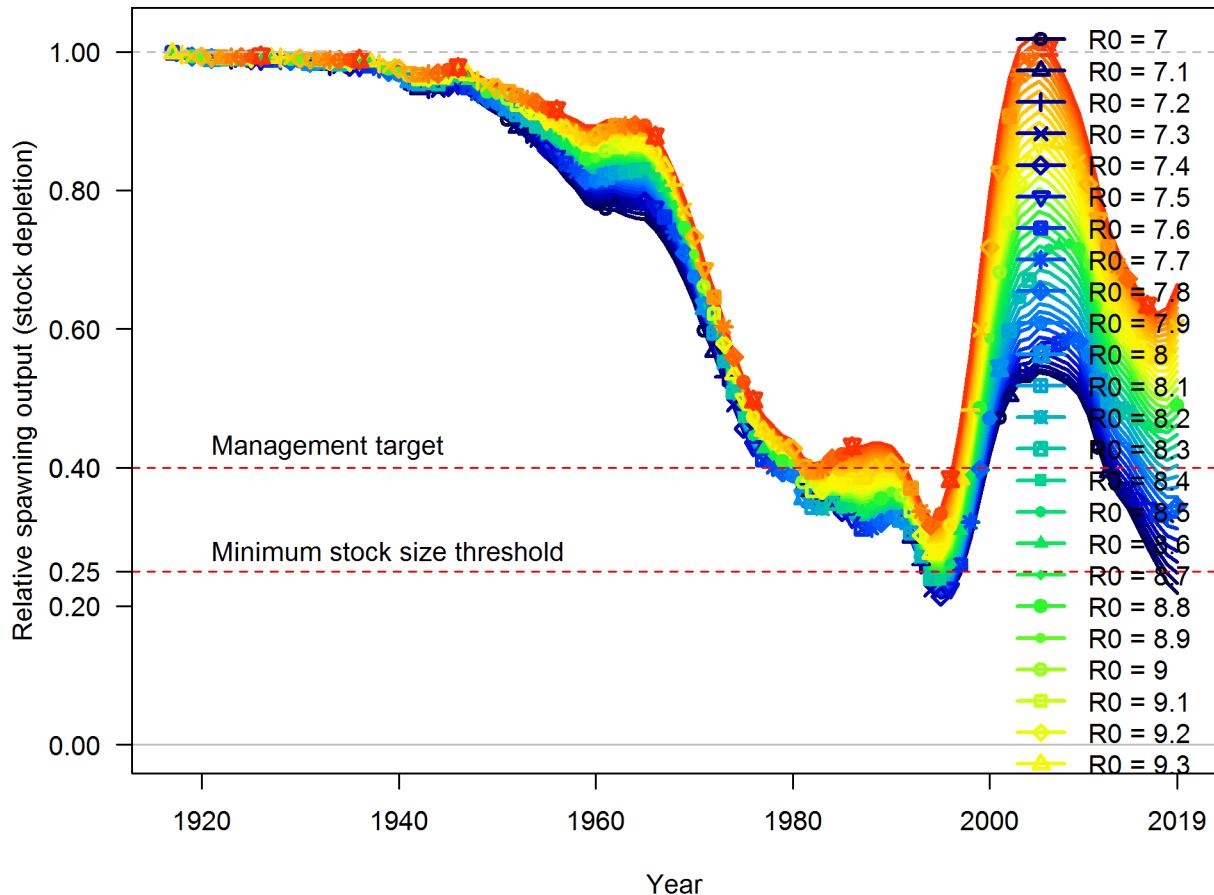

Figure 63: Trajectories of depletion across values of R_0 .

Changes in length-composition likelihoods by fleet

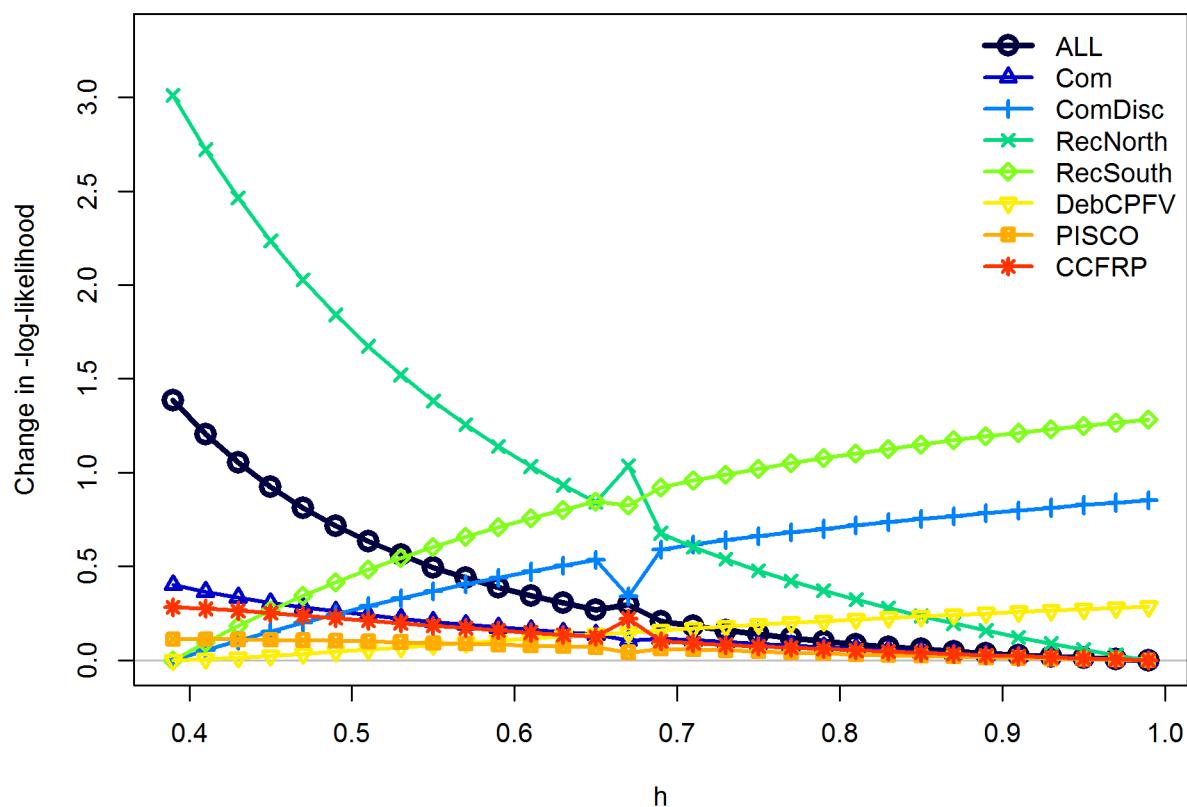

Figure 64: Likelihood profile across steepness values by fleet.

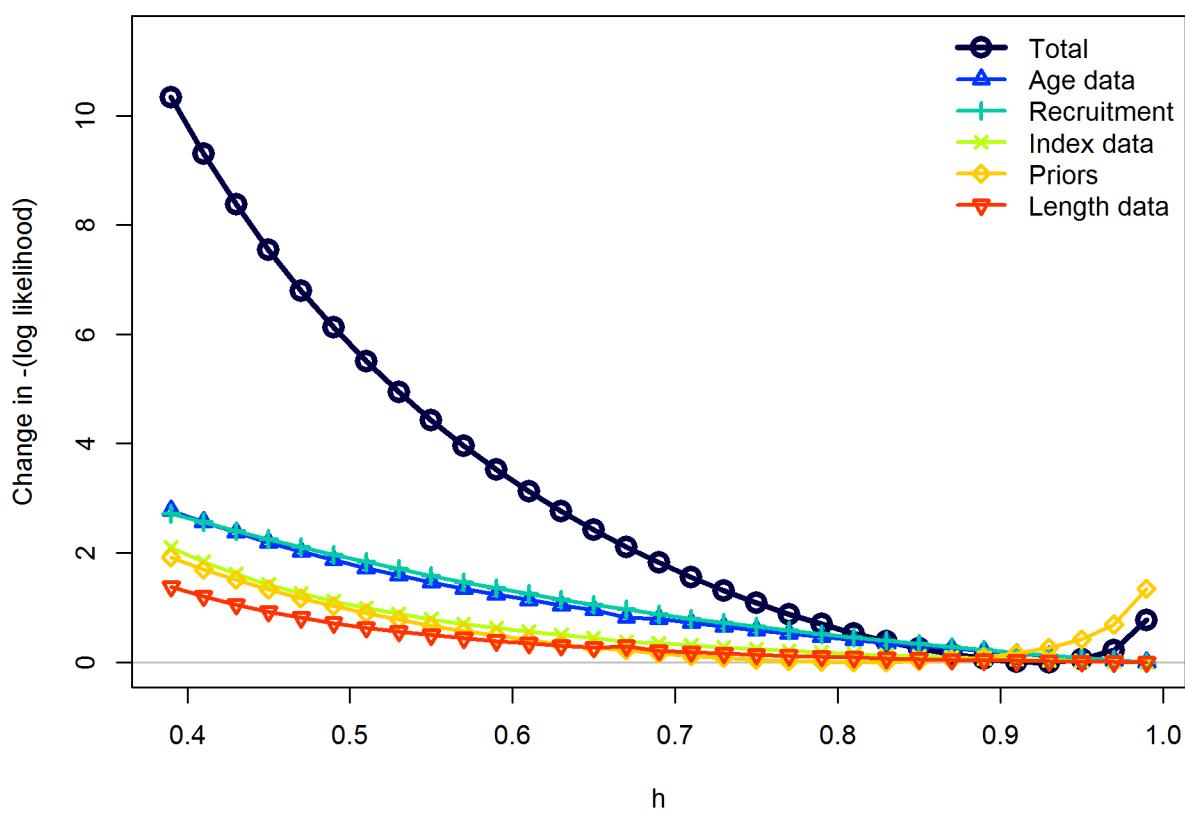

Figure 65: Likelihood profile across steepness values for each data type.

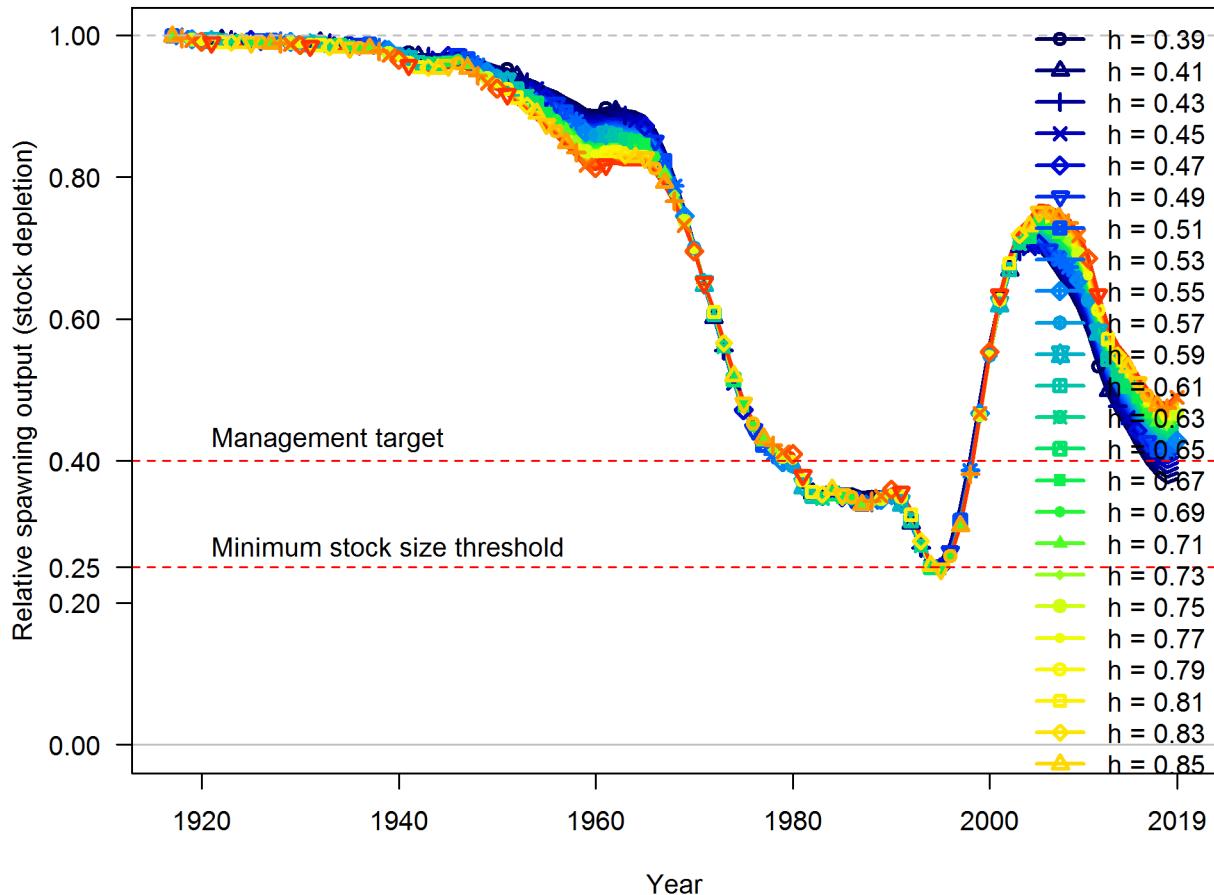

Figure 66: Trajectories of depletion across values of steepness.

Changes in length-composition likelihoods by fleet

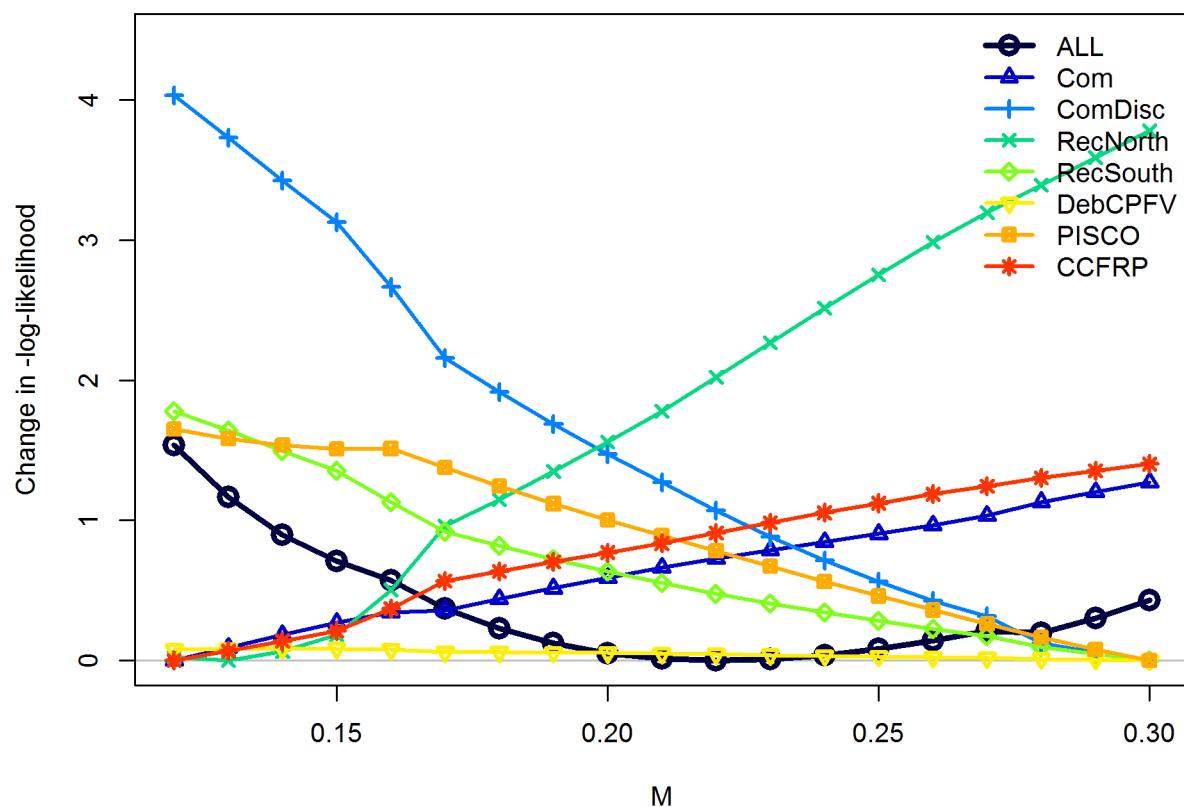

Figure 67: Likelihood profile across female natural mortality values by fleet.

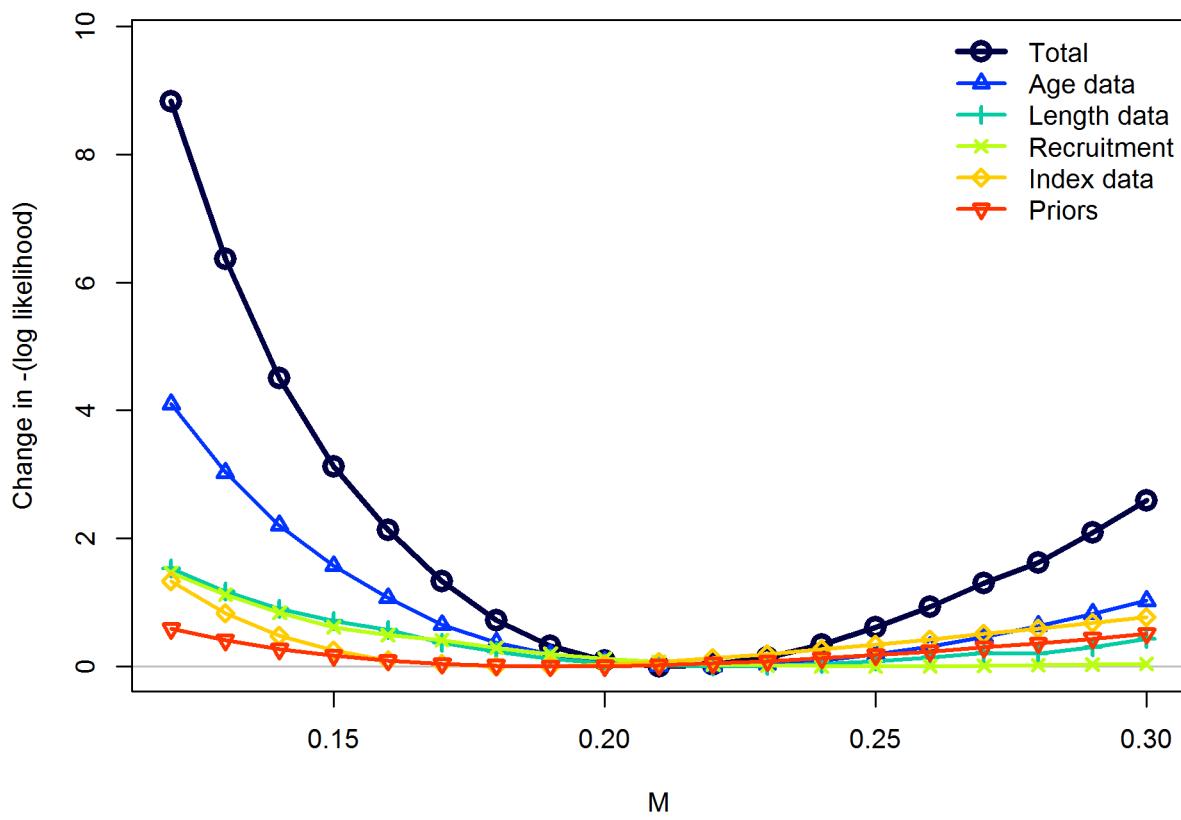

Figure 68: Likelihood profile across female natural mortality values for each data type.

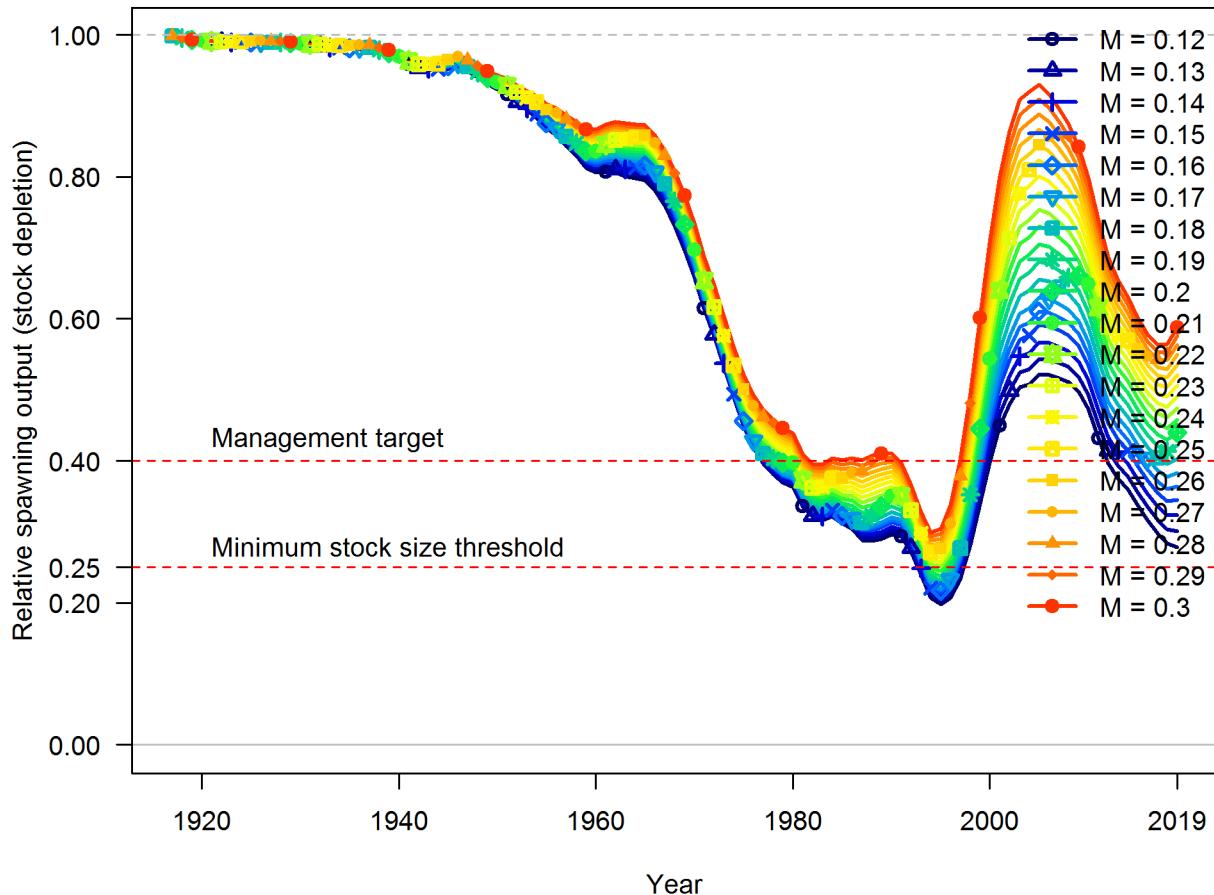

Figure 69: Trajectories of depletion across values of female natural mortality.

Spawning output with ~95% asymptotic intervals

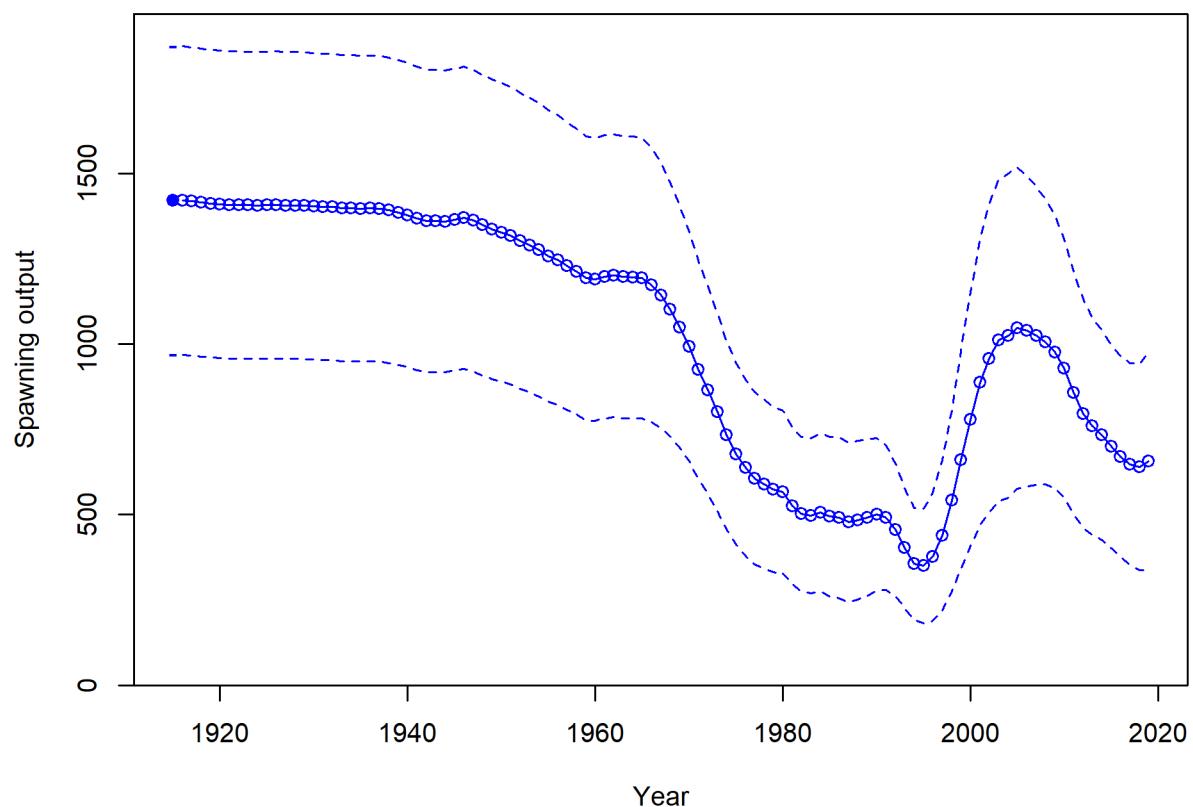

Figure 70: Estimated spawning biomass (mt) with approximate 95% asymptotic intervals.

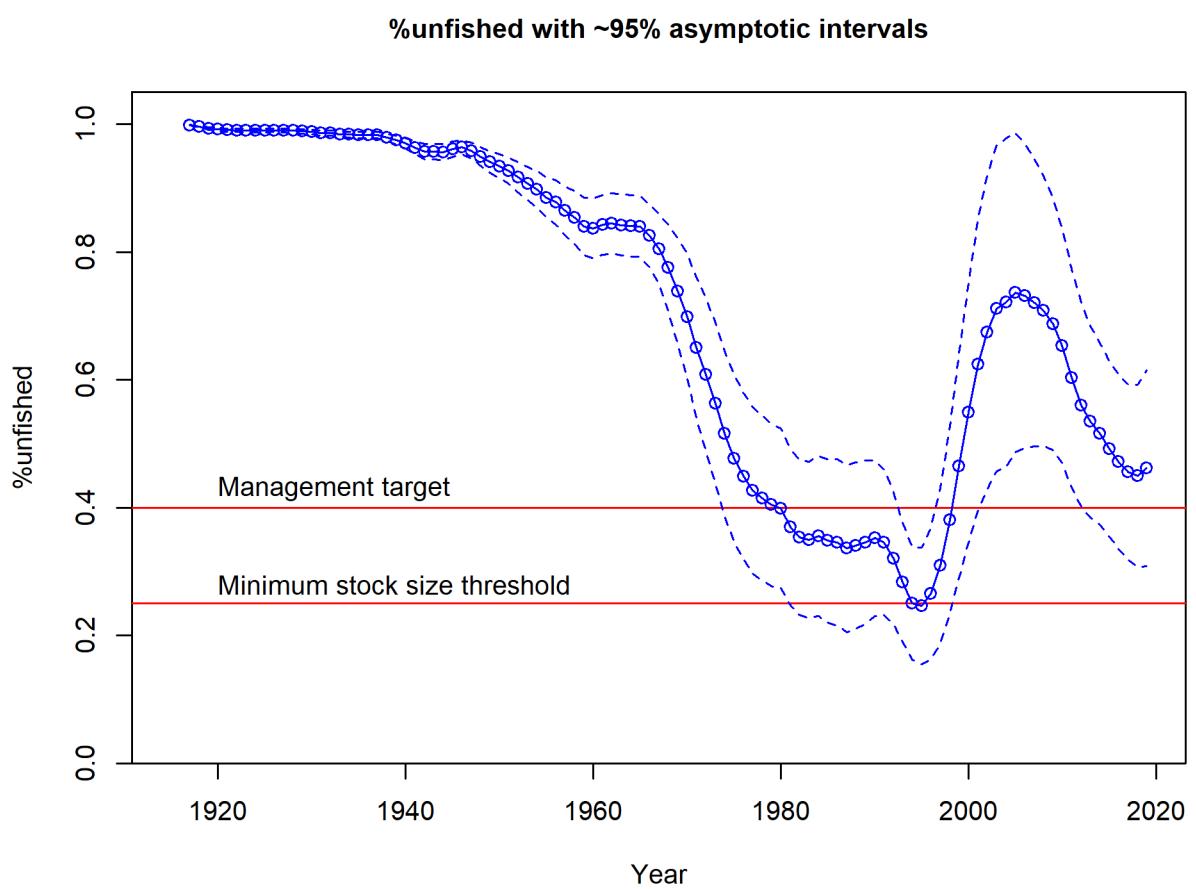

Figure 71: Estimated spawning depletion with approximate 95% asymptotic intervals.

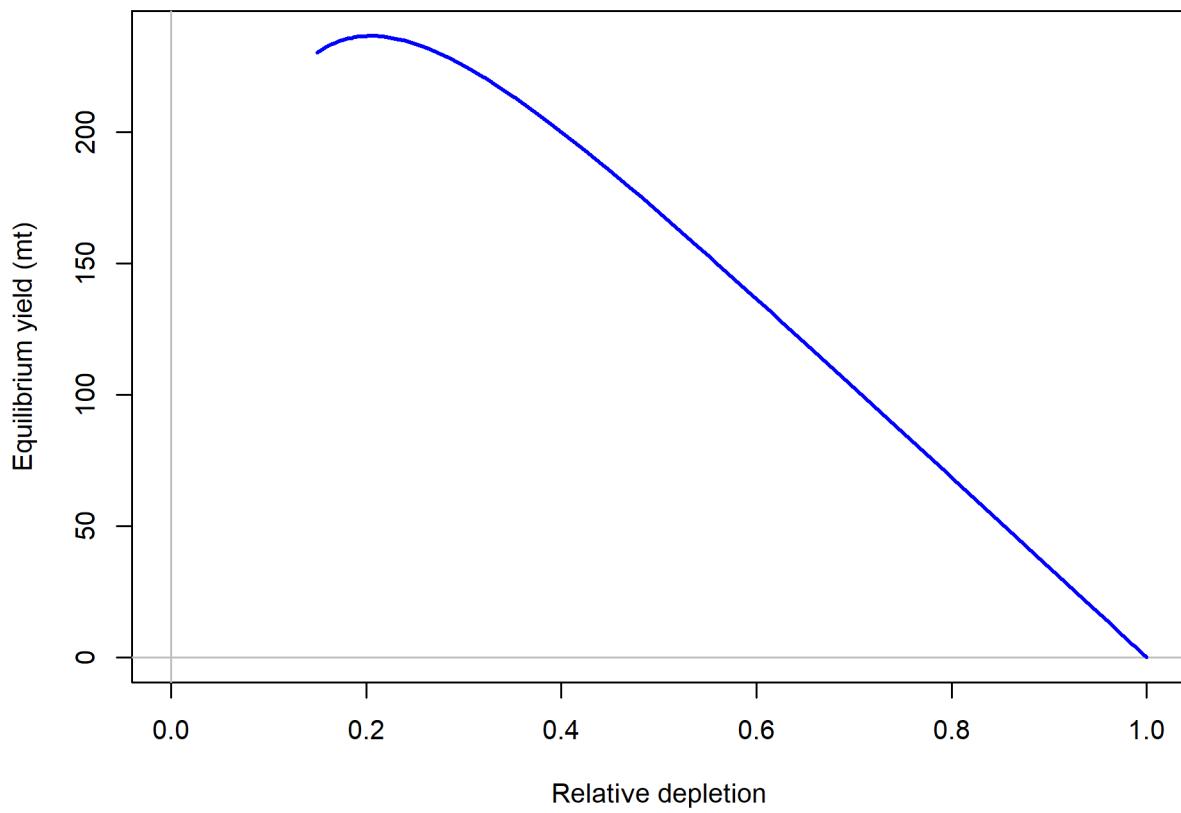

Figure 72: Equilibrium yield curve for the base case model. Values are based on the 2018 fishery selectivity and with steepness fixed at 0.718.

Figure B5

₁₇₃₂ Appendix C. Detailed fits to length composition data

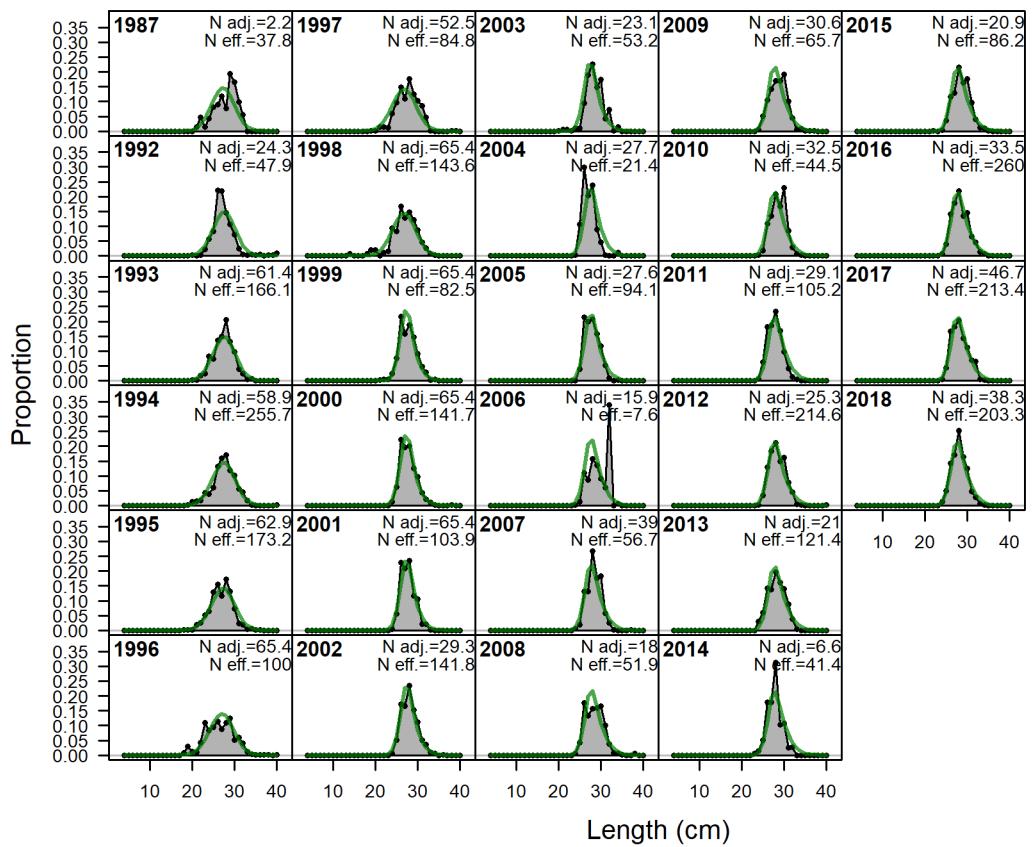

Figure C2: Length comps, retained, Com. ‘N adj.’ is the input sample size after data_weighting adjustment. N eff. is the calculated effective sample size used in the McAlister_Iannelli tuning method.

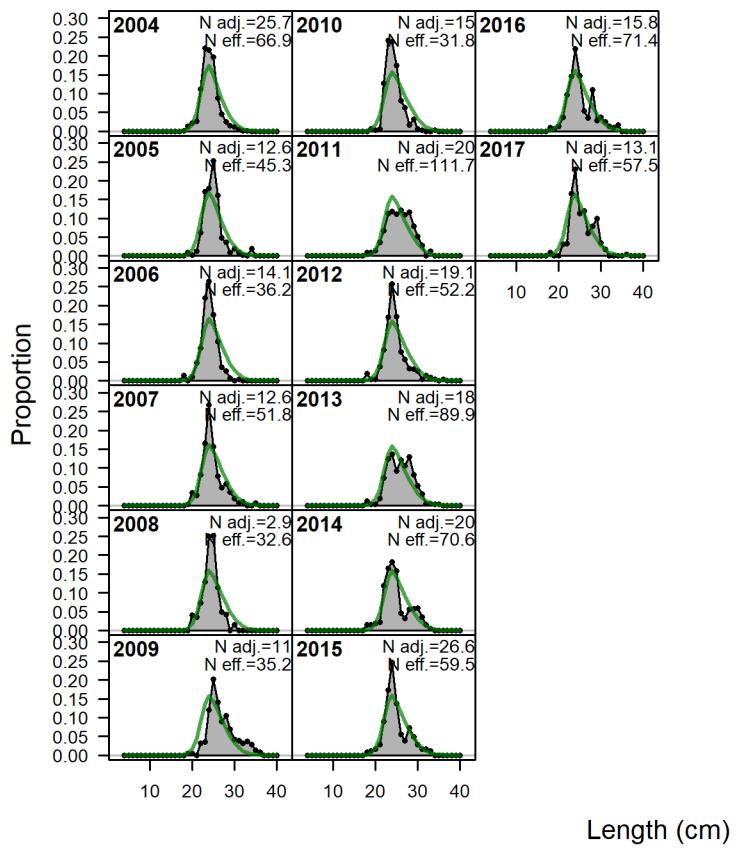

Figure C3: Length comps, retained, ComDisc. ‘N adj.’ is the input sample size after data_weighting adjustment. N eff. is the calculated effective sample size used in the McAlister_Iannelli tuning method.

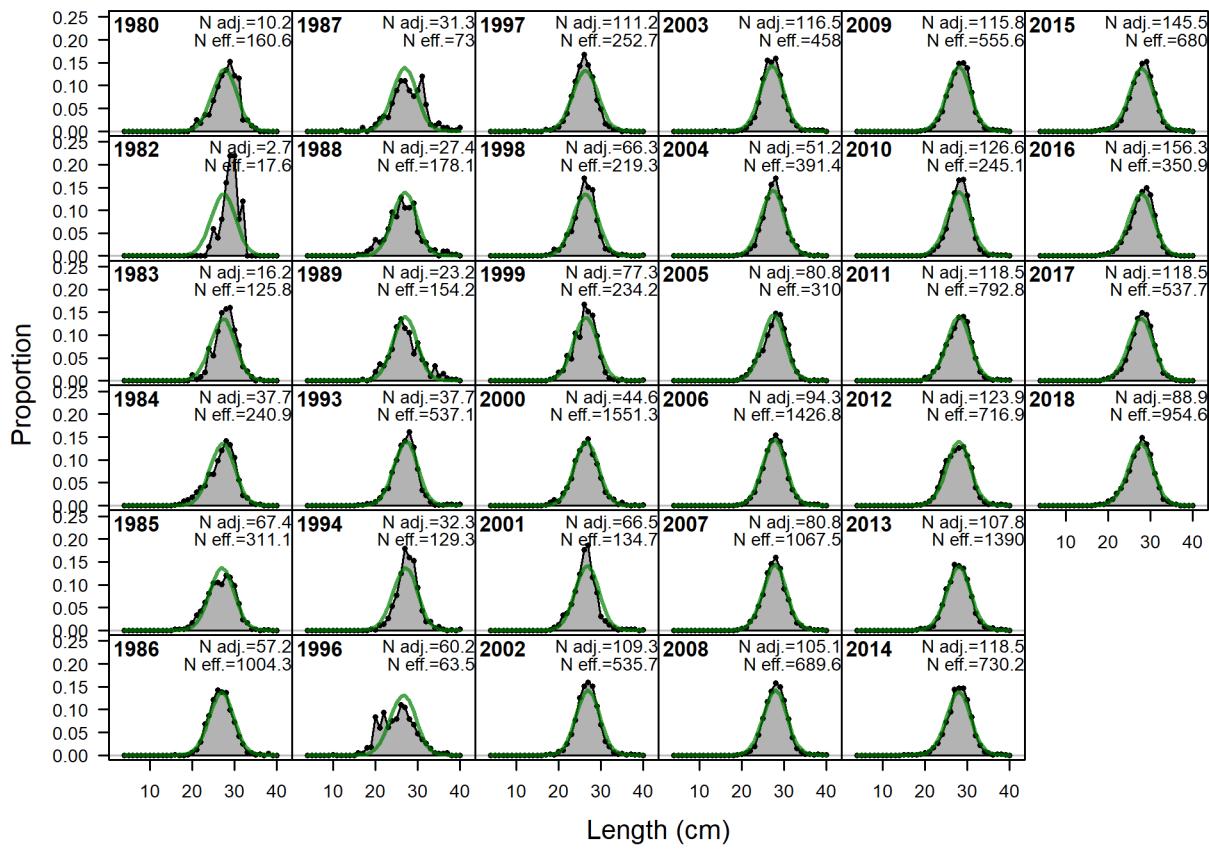

Figure C4: Length comps, whole catch, RecNorth. 'N adj.' is the input sample size after data_weighting adjustment. N eff. is the calculated effective sample size used in the McAllister_Iannelli tuning method.

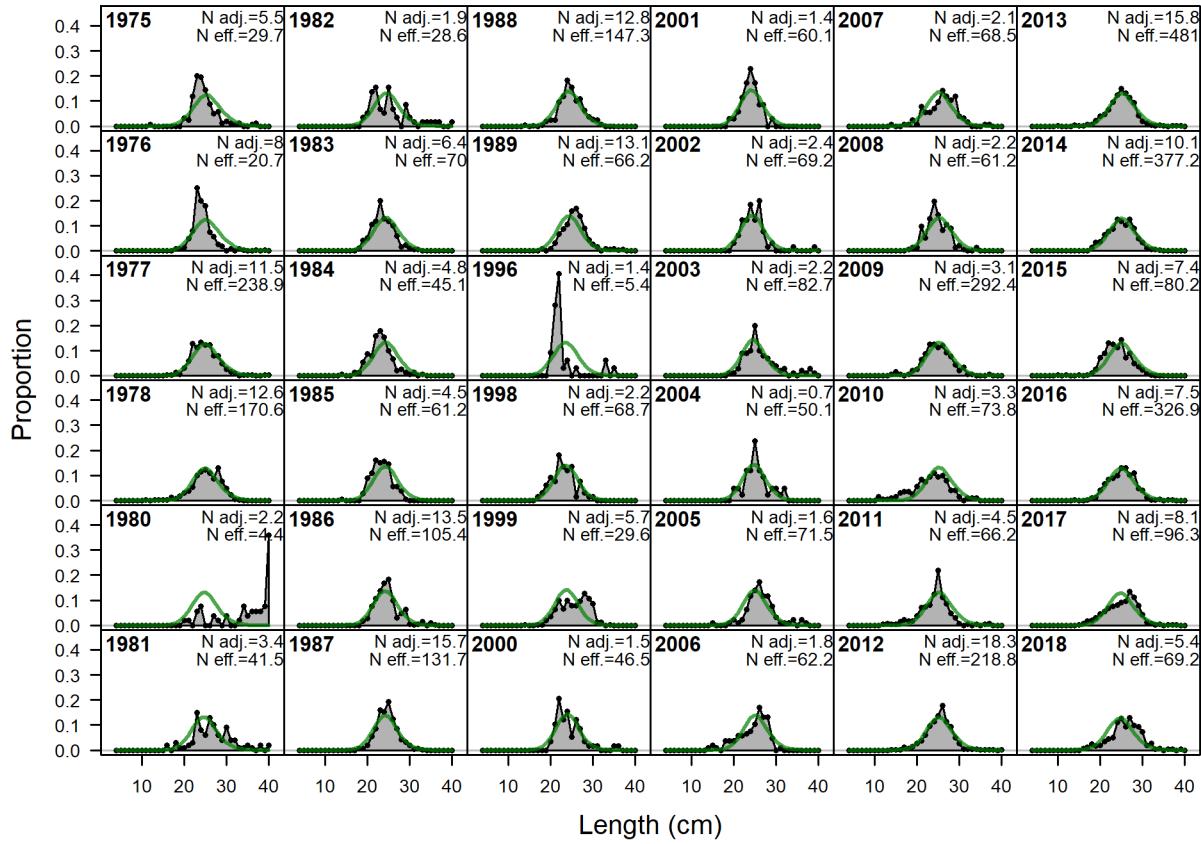

Figure C5: Length comps, whole catch, RecSouth. 'N adj.' is the input sample size after data_weighting adjustment. N eff. is the calculated effective sample size used in the McAllister_Iannelli tuning method.

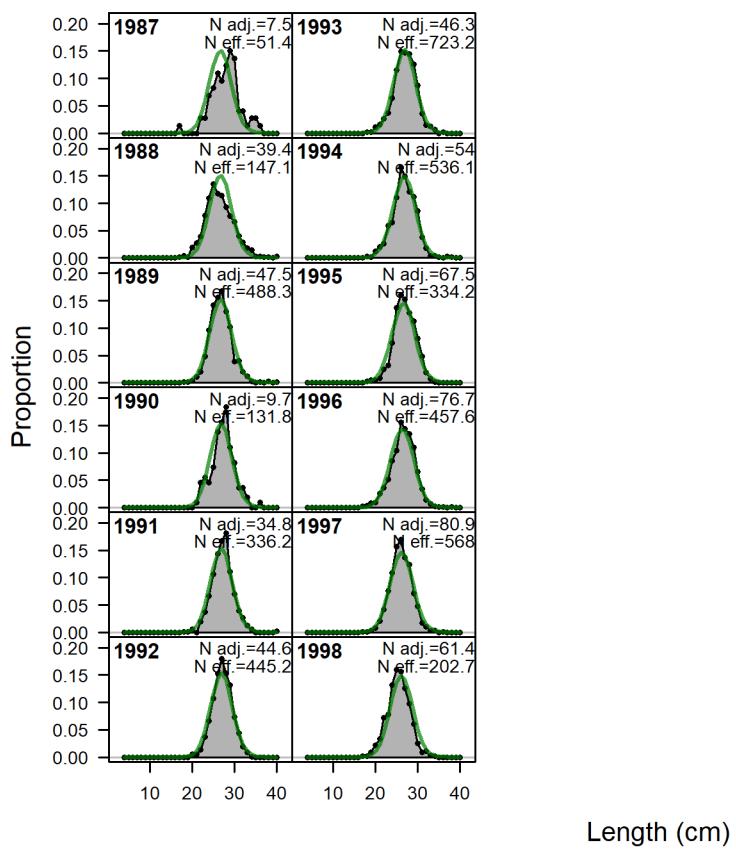

Figure C6: Length comps, whole catch, DebCPFV. 'N adj.' is the input sample size after data_weighting adjustment. N eff. is the calculated effective sample size used in the McAllister_Iannelli tuning method.

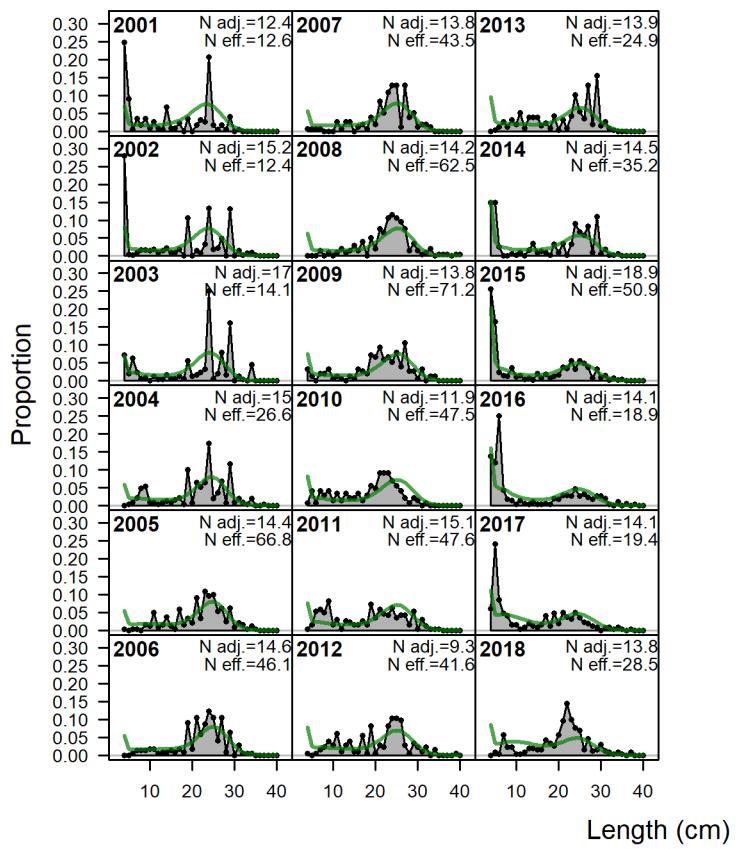

Figure C7: Length comps, whole catch, PISCO. ‘N adj.’ is the input sample size after data_weighting adjustment. N eff. is the calculated effective sample size used in the McAlister_Iannelli tuning method.

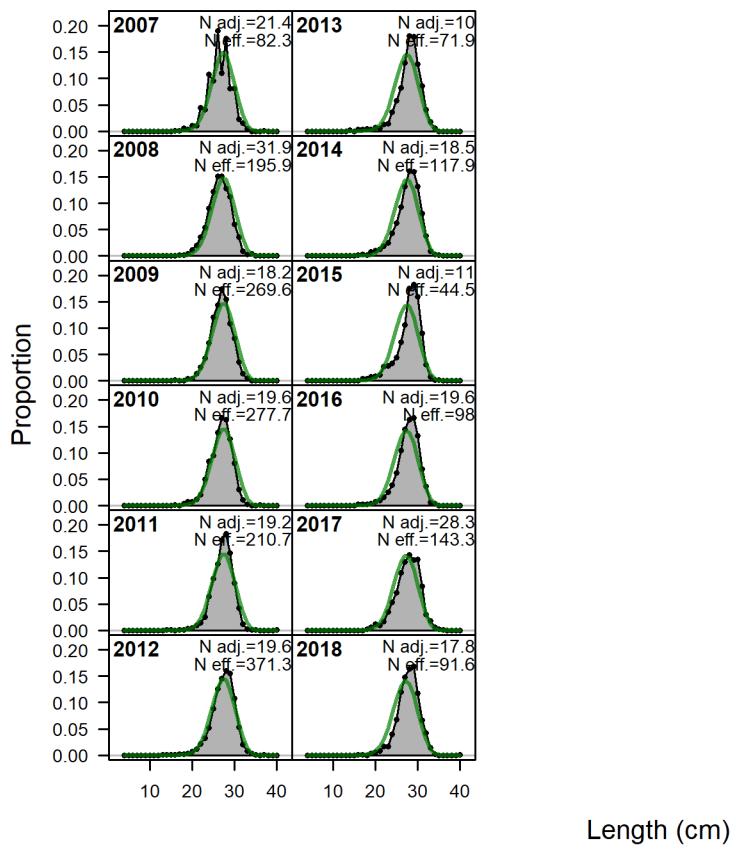

Figure C8: Length comps, whole catch, CCFRP. ‘N adj.’ is the input sample size after data_weighting adjustment. N eff. is the calculated effective sample size used in the McAlister_Iannelli tuning method.
